

# Data Mining Techniques

CS 6220 - Section 3 - Fall 2016

## Lecture 21: Review

Jan-Willem van de Meent

# Schedule

13	30 Nov	Bonus Topic: Deep Learning	#4 due
	02 Dec	Review	
14	07 Dec	(No Class)	
	09 Dec	Final Exam	
15	14 Dec	Project Presentations	Reports due
16	19 Dec	(Final grades posted)	

# Topics for Exam

## **Pre-Midterm**

- Probability
- Information Theory
- Linear Regression
- Classification
- Clustering

## **Post-Midterm**

- Topic Models
- Dimensionality Reduction
- Recommender Systems
- Association Rules
- Link Analysis
- Time Series
- Social Networks

# Post-Midterm Topics

# Topic Models

- Bag of words representations of documents
- Multinomial mixture models
- Latent Dirichlet Allocation
  - Generative model
  - Expectation Maximization (PLSA/PLSI)
  - Variational inference (high level)
- Perplexity
- Extensions (high level)
  - Dynamic Topic Models
  - Supervised LDA
  - Ideal Point Topic Models

# Dimensionality Reduction

## **Principal Component Analysis**

- Interpretation as minimization of reconstruction error
- Interpretation as maximization of captured variance
- Interpretation as EM in generative model
- Computation using eigenvalue decomposition
- Computation using SVD
- Applications (high-level)
  - Eigenfaces
  - Latent Semantic Analysis
    - Relationship to LDA
  - Multi-task learning
- Kernel PCA
  - Direct method vs modular method

# Dimensionality Reduction

- **Canonical Correlation Analysis**
  - Objective
  - Relationship to PCA
  - Regularized CCA
    - Motivation
    - Objective
- **Singular Value Decomposition**
  - Definition
  - Complexity
  - Relationship to PCA
- **Random Projections**
  - Johnson-Lindenstrauss Lemma

# Dimensionality Reduction

- **Stochastic Neighbor Embeddings**
  - Similarity definition in original space
  - Similarity definition in lower dimensional space
  - Definition of objective in terms of KL divergence
  - Gradient of objective

# Recommender Systems

- Motivation: The long tail of product popularity
- Content-based filtering
  - Formulation as a regression problem
  - User and item bias
  - Temporal effects
- Matrix Factorization
  - Formulation of recommender systems as matrix factorization
  - Solution through alternating least squares
  - Solution through stochastic gradient descent

# Recommender Systems

- **Collaborative filtering**

- (user, user) vs (item, item) similarity
  - pro's and cons of each approach
- Parzen-window CF
- Similarity measures
  - Pearson correlation coefficient
    - Regularization for small support
    - Regularization for small neighborhood
  - Jaccard similarity
    - Regularization
  - Observed/expected ratio
    - Regularization

# Association Rules

- Problem formulation and examples
  - Customer purchasing
  - Plagiarism detection
- Frequent Itemset
  - Definition of (fractional) support
- Association Rules
  - Confidence
  - Measures of interest
    - Added value
    - Mutual information

# Association Rules

- **A-priori**
  - Base principle
  - Algorithm
  - Self-joining and pruning of candidate sets
  - Maximal vs closed itemsets
  - Hash tree implementation for subset matching
  - I/O and memory limited steps
  - PCY method for reducing candidate sets
- **FP-Growth**
  - FP-tree construction
  - Pattern mining using conditional FP-trees
- Performance of A-priori vs FP-growth

# Aside: PCY vs PFP (parallel FP-Growth)

*I asked an actual expert*

Matteo  
Riondato

I notice that Spark MLib ships PFP as its main algorithm and I notice you benchmark against this as well. That said I can imagine there are might be different regimes where these algorithms are applicable. For example I notice you look at large numbers of transactions (order  $10^7$ ) but relatively small numbers of frequent items ( $10^3$ - $10^4$ ). The MMDS guys seem to emphasize the case where you cannot hold counts for all candidate pairs in memory, which presumably means numbers of items of order ( $10^5$ - $10^6$ ). Is it the case that once you are doing this at Walmart or Amazon scale, you in practice have to switch to PCY-variants?

Hi Jan,

This is a good question.

In my opinion, it is not true that if you have million of items then you need to use PCY-variants. FP-Growth and its many of variants are most likely going to perform better anyway, because available implementations have been seriously optimized. They are not really creating and storing pairs of candidates anyway, so that's not really the problem.

Hope this helps,

Matteo

**PARMA: a parallel randomized algorithm for approximate association rules mining in MapReduce**

[M Riondato](#), [JA DeBrabant](#), [R Fonseca](#)... - [Proceedings of the 21st ...](#), 2012 - [dl.acm.org](#)

Abstract Frequent Itemsets and Association Rules Mining (FIM) is a key task in knowledge discovery from data. As the dataset grows, the cost of solving this task is dominated by the component that depends on the number of transactions in the dataset. We address this issue

  - Calculating betweenness
  - Selecting number of clusters using the modularity

# Social Networks

- **Spectral clustering**

- Graph cuts
- Normalized cuts
- Laplacian Matrix
  - Definition in terms of Adjacency and Degree matrix
  - Properties of eigenvectors
    - Eigenvalues are  $\geq 0$
    - First eigenvector
      - Eigenvalue is 0
      - Eigenvector is  $[1 \dots 1]^T$
    - Second eigenvector (Fiedler vector)
      - Elements sum to 0
      - Eigenvalue is normalized sum of squared edge distances
- Use of first eigenvector to find normalized cut

# Pre-Midterm Topics

# Conjugate Distributions

**Binomial: Probability of  $m$  heads in  $N$  flips**

$$\text{Bin}(m|N, \mu) = \binom{N}{m} \mu^m (1 - \mu)^{N-m}$$

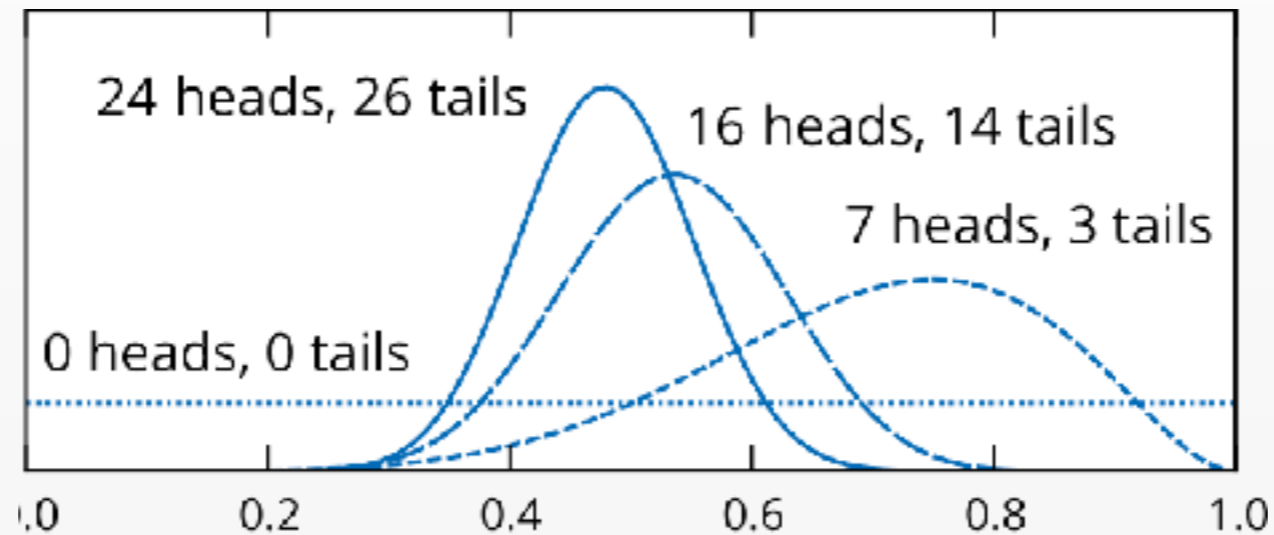

**Beta: Probability for bias  $\mu$**

$$\text{Beta}(\mu|a, b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \mu^{a-1} (1-\mu)^{b-1}$$

# Conjugate Distributions

## Posterior probability for $\mu$ given flips

$$p(\mu | m) = \frac{p(m, \mu)}{p(m)}$$

$$\propto \text{Bin}(m | N, \mu) \text{Beta}(\mu | a, b)$$

$$\propto \mu^{m+(a-1)} (1-\mu)^{(N-m)+(b-1)}$$

$$p(\mu | m) = \text{Beta}(a + m, b + (N - m))$$

# Information Theoretic Measures

## KL Divergence

$$KL(q \parallel p) = \sum_x q(x) \log \frac{q(x)}{p(x)}$$

## Perplexity

$$\text{Per}(p) = 2^{-\sum_x p(x) \log_2 p(x)}$$

## Mutual Information

$$I(X; Y) = \sum_{x,y} p(x,y) \log \frac{p(x,y)}{p(x)p(y)}$$

## Perplexity (of a model)

$$\text{Per}(q) = 2^{\sum_{n=1}^N \log_2 q(y_n)}$$

## Entropy

$$H(X) = -\sum_x p(x) \log p(x)$$

$$\hat{p}(y) = \frac{1}{N} \sum_{n=1}^N I[y_n = y]$$

$$H(\hat{p}, q) = -\sum_y \hat{p}(y) \log q(y)$$

$$\text{Per}(q) = e^{H(\hat{p}, q)}$$

# Loss Functions

squared loss:	$\frac{1}{2}(\mathbf{w}^\top \mathbf{x} - y)^2$	$y \in \mathbb{R}$	Linear Regression
zero-one:	$\frac{1}{4}(\text{Sign}(\mathbf{w}^\top \mathbf{x}) - y)^2$	$y \in \{-1, +1\}$	Perceptron
logistic loss:	$\log(1 + \exp(-y\mathbf{w}^\top \mathbf{x}))$	$y \in \{-1, +1\}$	Logistic Regression
hinge loss:	$\max\{0, 1 - y\mathbf{w}^\top \mathbf{x}\}$	$y \in \{-1, +1\}$	Soft SVMs

# Bias-Variance Trade-Off

Variance of what exactly?

# Bias-Variance Trade-Off

Assume classifier predicts expected value for  $y$

$$f(x) = \mathbb{E}_y[y|x] = \bar{y}$$

Squared loss of a classifier

$$\begin{aligned}\mathbb{E}_y[(y - f(x))^2|x] &= \mathbb{E}_y[(y - \bar{y} + \bar{y} - f(x))^2|x] \\ &= \mathbb{E}_y[(y - \bar{y})^2|x] + \mathbb{E}_y[(\bar{y} - f(x))^2|x] \\ &\quad + 2\mathbb{E}_y[(y - \bar{y})(\bar{y} - f(x))|x] \\ &= \mathbb{E}_y[(y - \bar{y})^2|x] + \mathbb{E}_y[(\bar{y} - f(x))^2|x] \\ &\quad + 2(\bar{y} - f(x))\mathbb{E}_y[(y - \bar{y})|x] \\ &= \mathbb{E}_y[(y - \bar{y})^2|x] + \mathbb{E}_y[(\bar{y} - f(x))^2|x] \\ &= \mathbb{E}_y[(y - \bar{y})^2|x] + (\bar{y} - f(x))^2\end{aligned}$$

# Bias-Variance Trade-Off

Training Data

$$T = \{(x^i, y^i) | i = 1, \dots, n\}$$

Expected value for  $y$

$$\bar{y} = \mathbb{E}_y[y|x]$$

Bias-Variance Decomposition

$$\begin{aligned} \mathbb{E}_{y,T}[(y - f_T(x))^2 | x] &= \mathbb{E}_y[(y - \bar{y})^2 | x] \\ &\quad + \mathbb{E}_{y,T}[(\bar{f}(x) - f_T(x))^2 | x] \\ &\quad + \mathbb{E}_y[(\bar{y} - \bar{f}(x))^2 | x] \\ &= \text{var}_y(y|x) + \text{var}_T(f(x)) + \text{bias}(f_T(x))^2 \end{aligned}$$

Classifier/Regressor

$$f_T = \underset{f}{\operatorname{argmin}} \sum_{i=1}^N \mathcal{L}(y_i, f(x^i))$$

Expected prediction

$$\bar{f}(x) = \mathbb{E}_T[f_T(x)]$$

# Bagging and Boosting

## Bagging

$$F_T^{\text{bag}}(x) = \frac{1}{B} \sum_{b=1}^B f_{T_b}(x)$$

- Sample  $B$  datasets  $T_b$  at random with replacement from the full data  $T$
- Train on classifiers independently on each dataset and average results
- Decreases variance (i.e. overfitting) does not affect bias (i.e. accuracy).

## Boosting

$$F^{\text{boost}}(x) = \frac{1}{B} \sum_{b=1}^B \alpha_b f_{w_b}(x)$$

- Sequential training
- Assign higher weight to previously misclassified data points
- Combines weighted weak learners (high bias) into a strong learner (low bias)
- Also some reduction of variance (in later iterations)
