Moving-head Disk Mechanism

- track $t$
- spindle
- sector $s$
- cylinder $c$
- read-write head
- platter
- arm
- arm assembly
- rotation
Overview of Mass Storage Structure

- **Magnetic disks** provide bulk of secondary storage of modern computers
  - Drives rotate at 60 to 250 times per second
  - **Transfer rate** is rate at which data flow between drive and computer
  - **Positioning time** (random-access time) is time to move disk arm to desired cylinder (seek time) and time for desired sector to rotate under the disk head (rotational latency)
  - **Head crash** results from disk head making contact with the disk surface
    - That’s bad
- Disks can be removable
- Drive attached to computer via **I/O bus**
  - Busses vary, including **EIDE, ATA, SATA, USB, Fibre Channel, SCSI, SAS, Firewire**
  - **Host controller** in computer uses bus to talk to **disk controller** built into drive or storage array
Magnetic Disks

- Platters range from .85” to 14” (historically)
  - Commonly 3.5”, 2.5”, and 1.8”
- Range from 30GB to 3TB per drive
- Performance
  - Transfer Rate – theoretical – 6 Gb/sec
  - Effective Transfer Rate – real – 1Gb/sec
  - Seek time from 3ms to 12ms – 9ms common for desktop drives
  - Average seek time measured or calculated based on 1/3 of tracks
  - Latency based on spindle speed
    - $1/(RPM \times 60)$
  - Average latency = $\frac{1}{2}$ latency
Magnetic Disk Performance

- **Access Latency** = **Average access time** = average seek time + average latency
  - For fastest disk 3ms + 2ms = 5ms
  - For slow disk 9ms + 5.56ms = 14.56ms

- Average I/O time = average access time + (amount to transfer / transfer rate) + controller overhead

  - For example to transfer a 4KB block on a 7200 RPM disk with a 5ms average seek time, 1Gb/sec transfer rate with a .1ms controller overhead =
    - 5ms + 4.17ms + 4KB / 1Gb/sec + 0.1ms =
    - 9.27ms + 4 / 131072 sec =
    - 9.27ms + .12ms = 9.39ms
The First Commercial Disk Drive

1956
IBM RAMDAC
computer included
the IBM Model 350
disk storage system

5M (7 bit) characters
50 x 24” platters
Access time = < 1 second
Magnetic Tape

- Was early secondary-storage medium
  - Evolved from open spools to cartridges
- Relatively permanent and holds large quantities of data
- Access time slow
- Random access ~1000 times slower than disk
- Mainly used for backup, storage of infrequently-used data, transfer medium between systems
- Kept in spool and wound or rewound past read-write head
- Once data under head, transfer rates comparable to disk
  - 140MB/sec and greater
- 200GB to 1.5TB typical storage
- Common technologies are LTO-{3,4,5} and T10000
Disk Structure

• Disk drives are addressed as large 1-dimensional arrays of **logical blocks**, where the logical block is the smallest unit of transfer

• The 1-dimensional array of logical blocks is mapped into the sectors of the disk sequentially
  • Sector 0 is the first sector of the first track on the outermost cylinder
  • Mapping proceeds in order through that track, then the rest of the tracks in that cylinder, and then through the rest of the cylinders from outermost to innermost
  • Logical to physical address should be easy
    • Except for bad sectors
    • Non-constant # of sectors per track via constant angular velocity
Disk Attachment

- Host-attached storage accessed through I/O ports talking to I/O busses

- SCSI itself is a bus, up to 16 devices on one cable, **SCSI initiator** requests operation and **SCSI targets** perform tasks
  - Each target can have up to 8 **logical units** (disks attached to device controller)

- FC is high-speed serial architecture
  - Can be switched fabric with 24-bit address space – the basis of **storage area networks (SANs)** in which many hosts attach to many storage units

- I/O directed to bus ID, device ID, logical unit (LUN)
Storage Array

- Can just attach disks, or arrays of disks

- Storage Array has controller(s), provides features to attached host(s)
  - Ports to connect hosts to array
  - Memory, controlling software (sometimes NVRAM, etc)
  - A few to thousands of disks
  - RAID, hot spares, hot swap (discussed later)
  - Shared storage -> more efficiency
  - Features found in some file systems
    - Snapshots, clones, thin provisioning, replication, deduplication, etc
Network-Attached Storage

- Network-attached storage (NAS) is storage made available over a network rather than over a local connection (such as a bus)
  - Remotely attaching to file systems
- NFS and CIFS are common protocols
- Implemented via remote procedure calls (RPCs) between host and storage over typically TCP or UDP on IP network
- iSCSI protocol uses IP network to carry the SCSI protocol
  - Remotely attaching to devices (blocks)
Disk Scheduling

• The operating system is responsible for using hardware efficiently — for the disk drives, this means having a fast access time and disk bandwidth

• Minimize seek time

• Seek time $\approx$ seek distance

• Disk **bandwidth** is the total number of bytes transferred, divided by the total time between the first request for service and the completion of the last transfer
Disk Scheduling (Cont.)

• There are many sources of disk I/O request
  • OS, System processes, Users processes
• I/O request includes input or output mode, disk address, memory address, number of sectors to transfer
• OS maintains queue of requests, per disk or device
• Idle disk can immediately work on I/O request, busy disk means work must queue
  • Optimization algorithms only make sense when a queue exists
• Note that drive controllers have small buffers and can manage a queue of I/O requests (of varying “depth”)
• Several algorithms exist to schedule the servicing of disk I/O requests
• The analysis is true for one or many platters
• We illustrate scheduling algorithms with a request queue (0-199) 98, 183, 37, 122, 14, 124, 65, 67, Head pointer 53
FCFS

Illustration shows total head movement of 640 cylinders

queue = 98, 183, 37, 122, 14, 124, 65, 67
head starts at 53
SSTF

- Shortest Seek Time First selects the request with the minimum seek time from the current head position

- SSTF scheduling is a form of SJF scheduling; may cause starvation of some requests

- Illustration shows total head movement of 236 cylinders
SSTF (Cont.)

queue = 98, 183, 37, 122, 14, 124, 65, 67
head starts at 53
SCAN

- The disk arm starts at one end of the disk, and moves toward the other end, servicing requests until it gets to the other end of the disk, where the head movement is reversed and servicing continues.

- **SCAN algorithm** Sometimes called the *elevator algorithm*

- Illustration shows total head movement of 208 cylinders

- But note that if requests are uniformly dense, largest density at other end of disk and those wait the longest
SCAN (Cont.)

queue = 98, 183, 37, 122, 14, 124, 65, 67
head starts at 53
C-SCAN

• Provides a more uniform wait time than SCAN

• The head moves from one end of the disk to the other, servicing requests as it goes
  • When it reaches the other end, however, it immediately returns to the beginning of the disk, without servicing any requests on the return trip

• Treats the cylinders as a circular list that wraps around from the last cylinder to the first one

• Total number of cylinders?
C-SCAN (Cont.)

queue = 98, 183, 37, 122, 14, 124, 65, 67
head starts at 53
C-LOOK

• LOOK a version of SCAN, C-LOOK a version of C-SCAN

• Arm only goes as far as the last request in each direction, then reverses direction immediately, without first going all the way to the end of the disk

• Total number of cylinders?
C-LOOK (Cont.)

queue = 98, 183, 37, 122, 14, 124, 65, 67
head starts at 53
Selecting a Disk-Scheduling Algorithm

• SSTF is common and has a natural appeal

• SCAN and C-SCAN perform better for systems that place a heavy load on the disk
  • Less starvation

• Performance depends on the number and types of requests

• Requests for disk service can be influenced by the file-allocation method
  • And metadata layout

• The disk-scheduling algorithm should be written as a separate module of the operating system, allowing it to be replaced with a different algorithm if necessary

• Either SSTF or LOOK is a reasonable choice for the default
Disk Management

- **Low-level formatting**, or **physical formatting** — Dividing a disk into sectors that the disk controller can read and write
  - Each sector can hold header information, plus data, plus error correction code (ECC)
  - Usually 512 bytes of data but can be selectable

- To use a disk to hold files, the operating system still needs to record its own data structures on the disk
  - **Partition** the disk into one or more groups of cylinders, each treated as a logical disk
  - **Logical formatting** or “making a file system”
  - To increase efficiency most file systems group blocks into **clusters**
    - Disk I/O done in blocks
Booting from a Disk in Windows 2000

The diagram illustrates the partitioning of a disk with four partitions. The Master Boot Record (MBR) is located at the beginning of the disk. The boot code and partition table are stored in the boot partition, which is typically the first partition. The other partitions are used for the operating system and data storage.
RAID Structure

- RAID – multiple disk drives provides reliability via **redundancy**

- Increases the **mean time to failure**

- Frequently combined with **NVRAM** to improve write performance

- RAID is arranged into six different levels
RAID (Cont.)

• Several improvements in disk-use techniques involve the use of multiple disks working cooperatively

• Disk *striping* uses a group of disks as one storage unit

• RAID schemes improve performance and improve the reliability of the storage system by storing redundant data
  • *Mirroring* or *shadowing* (RAID 1) keeps duplicate of each disk
  • Striped mirrors (RAID 1+0) or mirrored stripes (RAID 0+1) provides high performance and high reliability
    • *Block interleaved parity* (RAID 4, 5, 6) uses much less redundancy
  • RAID within a storage array can still fail if the array fails, so automatic *replication* of the data between arrays is common
  • Frequently, a small number of *hot-spare* disks are left unallocated, automatically replacing a failed disk and having data rebuilt
RAID Levels

(a) RAID 0: non-redundant striping.

(b) RAID 1: mirrored disks.

(c) RAID 2: memory-style error-correcting codes.

(d) RAID 3: bit-interleaved parity.

(e) RAID 4: block-interleaved parity.

(f) RAID 5: block-interleaved distributed parity.

(g) RAID 6: P + Q redundancy.
RAID (0 + 1) and (1 + 0)

a) RAID 0 + 1 with a single disk failure.

b) RAID 1 + 0 with a single disk failure.
