The main goal I want my UI to achieve is for patients to know clearly when they should be taking their pills and for how long. There are many issues, specifically with people who need to take a lot of meds, where people forget to take their medications. People who have certain conditions could be taking an immense amount of pills and information can be lost since the majority of the time these people have no experience in the medical field at all. No matter the patient’s professional background, everyone has busy schedules and could use a tool to make it easier to track their medication.

The solution to these issues would include a very simplistic design where the user can easily add medications and their duration to an application. Once added their could be a calendar view with times and dosages for each drug that need to be taken and when. With this design people of all ages would be able to easily record and track their medication and ensure they are efficient with their schedule and drugs. Possible other functions include descriptions of each drug and what should be done (if anything) before taking them. This function could simply be a text box that the user inputs when adding the drug to the calendar. With this application medication will be properly taken and tracked for patients. The medical field and what it requires is very complex, and this tool will help alleviate some of that pressure.
