Lecture 3: Expressions

Key Concepts:

syntax and semantics
expressed and denoted values
expressions
environment
specifying the behavior of expressions
let expressions
implementation using PLT Scheme and its module system
procedures
formal parameter, bound variable
actual parameters, operand, argument
closures
letrec
poor man’s letrec
multiple arguments, multiple declarations
3.1 LET: a simple language

(let-lang) (All these interpreters are in http://www.ccs.neu.edu/course/csg111/interps/lecture03/)

3.1.1 Specification of Syntax

Syntax for the LET language

\[
\begin{align*}
\text{Program} & \ ::= \ \text{Expression} \\
\text{Expression} & \ ::= \ \text{Number} \\
\text{Expression} & \ ::= \ -(\text{Expression}, \text{Expression}) \\
\text{Expression} & \ ::= \ \text{zero?} \ \text{Expression} \\
\text{Expression} & \ ::= \ \text{if} \ \text{Expression} \ \text{then} \ \text{Expression} \ \text{else} \ \text{Expression} \\
\text{Expression} & \ ::= \ \text{Identifier} \\
\text{Expression} & \ ::= \ \text{let} \ \text{Identifier} = \ \text{Expression} \ \text{in} \ \text{Expression} \\
\end{align*}
\]

> (scan&parse "-(55, -(22,11))")
#(struct:a-program
  #(struct:diff-exp
    #(struct:const-exp 55)
    #(struct:diff-exp
      #(struct:const-exp 22)
      #(struct:const-exp 11))))

2
3.1.2 Specification of Values

An important part of the specification of any programming language is the set of values that the language manipulates. Each language has at least two such sets: the expressed values and the denoted values. The expressed values are the possible values of expressions, and the denoted values are the values bound to variables.

In Scheme, for example, there are many kinds of expressed values, such as numbers, pairs, characters, and strings. However every Scheme variable denotes a location that is modifiable using `set!`, so there is only one kind of denoted value: a location containing expressed values.

In our language, the expressed and denoted values will be the same:

\[
\text{ExpVal} = \text{Int} + \text{Bool} \\
\text{DenVal} = \text{Int} + \text{Bool}
\]

We model this using `define-datatype`

```scheme
(define-datatype expval expval?
  (num-val
   (value number?))
  (bool-val
   (boolean boolean?)))
```

We typically use extractors with `expval`:

```scheme
(define expval->num
 (lambda (v)
   (cases expval v
     (num-val (num) num)
     (else (expval-extractor-error 'num v))))

(define expval->bool
 (lambda (v)
   (cases expval v
     (bool-val (bool) bool)
     (else (expval-extractor-error 'bool v))))
```
(define expval-extractor-error
  (lambda (variant value)
    (eopl:error 'expval-extractors "Looking for a \~s, found \~s"
      variant value))))
3.1.3 Environments

If we’re going to evaluate expressions containing variables, we’ll need to know the value associated with each variable. We’ll do this by keeping those values in an environment.

An environment is a function whose domain is a finite set of variables and whose range is the denoted values.

- \( \rho \) ranges over environments.
- \([\]\) denotes the empty environment.
- \([x = v]\rho\) denotes \((\text{extend-env } x \ v \ \rho)\).
- \([x_1 = v_1, x_2 = v_2]\rho\) abbreviates \([x_1 = v_1]\([x_2 = v_2]\rho\). etc.
- \([x_1 = v_1, x_2 = v_2, \ldots]\) denotes the environment in which the value of \(x_1\) is \(v_1\), etc.

We’ll use indentation to improve readability, eg:

\[
[x=3] \\
[y=7] \\
[u=5] \rho
\]

to abbreviate

\[
(\text{extend-env } x \ 3 \\
(\text{extend-env } y \ 7 \\
(\text{extend-env } u \ 5 \ \rho)))
\]
3.1.4 Specifying the Behavior of Expressions

6 kinds of expressions in our language: one for each production with Expression as its left-hand side.

Interface for expressions will contain seven procedures: six constructors and one observer.

We use \texttt{exp\_val} to denote the set of expressed values.

\textbf{Interface for Expressions}

\textit{constructors:}
\begin{itemize}
  \item \texttt{const-exp} : int \rightarrow \texttt{expression}
  \item \texttt{zero?-exp} : \texttt{expression} \rightarrow \texttt{expression}
  \item \texttt{if-exp} : \texttt{expression} \times \texttt{expression} \times \texttt{expression} \rightarrow \texttt{expression}
  \item \texttt{diff-exp} : \texttt{expression} \times \texttt{expression} \rightarrow \texttt{expression}
  \item \texttt{var-exp} : \texttt{symbol} \rightarrow \texttt{expression}
  \item \texttt{let-exp} : \texttt{symbol} \times \texttt{expression} \times \texttt{expression} \rightarrow \texttt{expression}
\end{itemize}

\textit{observer:}
\begin{itemize}
  \item \texttt{value-of} : \texttt{expression} \times \texttt{environment} \rightarrow \texttt{exp\_val}
\end{itemize}
Now need to specify behavior of the functions in this interface.
Specification will consist of assertions of the form

\[(\text{value-of } e \ p) = v\]

meaning that the value of expression \( e \) in environment \( p \) should be \( v \).
We write down rules of inference and equations, like those in chapter 1, that will enable us to derive such assertions.

\[
(\text{value-of (const-exp n) } p) = n
\]

\[
(\text{value-of (var-exp x) } p) = (\text{apply-env } p \ x)
\]

\[
(\text{value-of (diff-exp e_1 e_2) } p) = (-
(\text{value-of e_1 } p)
(\text{value-of e_2 } p))
\]
3.1.5 An Example

Let $\rho = [x=10, v=5, i=1]$.
We write $\langle\langle e \rangle\rangle$ to denote the AST for expression $e$.
Then

$$(\text{value-of-expression} \langle\langle -(x, 3) - (v, i) \rangle\rangle \rho)$$

$$= (-$$
$$\quad (\text{value-of-expression} \langle\langle x \rangle\rangle \rho)$$
$$\quad (\text{value-of-expression} \langle\langle v, i \rangle\rangle \rho))$$

$$= (-$$
$$\quad (-$$
$$\quad \quad 10$$
$$\quad \quad (\text{value-of-expression} \langle\langle 3 \rangle\rangle \rho))$$
$$\quad (\text{value-of-expression} \langle\langle v, i \rangle\rangle \rho))$$

$$= (-$$
$$\quad (-$$
$$\quad \quad \quad \quad 10$$
$$\quad \quad \quad \quad 3)$$
$$\quad (\text{value-of-expression} \langle\langle v, i \rangle\rangle \rho))$$

$$= (-$$
$$\quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad 7$$
$$\quad \quad \quad \quad \quad \quad \quad \quad (\text{value-of-expression} \langle\langle v, i \rangle\rangle \rho))$$
= (-
  7
  (-
    (value-of-expression <<v>> ρ)
    (value-of-expression <<i>> ρ)))

= (-
  7
  (-
    5
    (value-of-expression <<i>> ρ)))

= (-
  7
  (-
    5
    1))

= (-
  7
  4)

= 3
3.1.6 Specifying the Behavior of Programs

In our language, a whole program is just an expression. In order to find the value of such an expression, we need to specify the values of the free variables in the program. So the value of a program is just the value of that expression in a suitable initial environment. We choose our initial environment to be \([i=1, v=5, x=10]\).

\[(\text{value-of-program } e) = (\text{value-of } e \ [i=1, v=5, x=10])\]
3.1.7 Specifying Conditionals

The next portion of the language introduces an interface for booleans in our language. The language has one constructor of booleans, \texttt{zero?}, and one observer of booleans, the \texttt{if} expression.

The value of a \texttt{zero?} expression is a true value if and only if the value of its operand is zero.

\[
\text{(value-of } e_1 \text{ } \rho) = v \\
\text{(value-of } (\text{zero?-exp } e_1) \text{ } \rho) \\
= \begin{cases} 
  \text{(bool-val } \#\text{t}) & \text{if } (\text{expval->num } v) = 0 \\
  \text{(bool-val } \#\text{f}) & \text{if } (\text{expval->num } v) \neq 0
\end{cases}
\]

We use \texttt{bool-val} as a constructor to turn a boolean into an expressed value, and \texttt{expval->num} as an extractor to check to see whether an expressed value is an integer, and if so, to return the integer.

An \texttt{if} expression is an observer of boolean values.

\[
\text{(value-of } e_1 \text{ } \rho) = v \\
\text{(value-of } (\text{if-exp } e_1 e_2 e_3) \text{ } \rho) \\
= \begin{cases} 
  \text{(value-of } e_2 \text{ } \rho) & \text{if } (\text{expval->bool } v) = \#\text{t} \\
  \text{(value-of } e_3 \text{ } \rho) & \text{if } (\text{expval->bool } v) = \#\text{f}
\end{cases}
\]
Rules of inference like this make the intended behavior of any individual expression easy to specify, but they are not very good for displaying a deduction.

So we recast our rules as equations.

Can then use substitution of equals for equals to display a calculation.

\[
(value\text{-}of\ (if\text{-}exp\ e_1\ e_2\ e_3\ \rho)) \\
= (if\ (expval\rightarrow\text{bool}\ (value\text{-}of\ e_1\ \rho)) \\
\quad (value\text{-}of\ e_2\ \rho) \\
\quad (value\text{-}of\ e_3\ \rho))
\]
**An Example**  Let $\rho = [x=66, y=22]$.

\[
\begin{align*}
\text{value-of} & \quad \langle\text{if}\ zero?(-(x,11))\ \text{then}\ -(y,2)\ \text{else}\ -(y,4)\rangle \\
& \quad \rho \\
& = (\text{if} \ (\text{expval}\rightarrow\text{bool} \ (\text{value-of} \ \langle\text{zero?}\(-(x,11))\rangle \ \rho)) \\
& \quad (\text{value-of} \ \langle-(y,2)\rangle \ \rho) \\
& \quad (\text{value-of} \ \langle-(y,4)\rangle \ \rho)) \\
& = (\text{if} \ (\text{expval}\rightarrow\text{bool} \ (\text{bool-val} \ #f)) \\
& \quad (\text{value-of} \ \langle-(y,2)\rangle \ \rho) \\
& \quad (\text{value-of} \ \langle-(y,4)\rangle \ \rho)) \\
& = (\text{if} \ (#f) \\
& \quad (\text{value-of} \ \langle-(y,2)\rangle \ \rho) \\
& \quad (\text{value-of} \ \langle-(y,4)\rangle \ \rho)) \\
& = (\text{value-of} \ \langle-(y,4)\rangle \ \rho) \\
& = 18
\end{align*}
\]
3.1.8 Adding let

Examples

```plaintext
let x = 5
in -(x,3)

let x = 5
in let y = 3
  in -(x,y)

let z = 5
in let x = 3
  in let y = -(x,1) % here x = 3
    in let x = 4
      in -(z,-(x,y)) % here x = 4
```

The let variable is bound in the body.

Specification  As a rule of inference:

\[
\frac{(value-of \ e_1 \ \rho) = v_1}{(value-of \ (let-exp \ var \ e_1 \ e_2) \ \rho) = (value-of \ e_2 \ [var = v_1] \rho)}
\]

Or as an equation:

\[
(value-of \ (let-exp \ x \ e_1 \ e_2) \ \rho)
= (value-of \ e_2 \ [x=(value-of \ e_1 \ \rho)] \rho)
\]
An example:
Let $\rho = [z = 7]$. Then

\[
\begin{align*}
\text{(value-of-expression} & \text{ <<let } x = 5 \\
& \quad \text{ in let } y = -(z,3) \\
& \quad \quad \text{ in } -(x,y),z \text{>> } \rho) \\
= \text{(value-of-expression} & \text{ <<let } y = -(z,3) \\
& \quad \text{ in } -(x,y),z \text{>> } [x = 5] \rho) \\
\text{(Let } \rho_1 = [x=5] \rho) \\
= \text{(value-of-expression} & \text{ <<-}(x,y),z \text{>>} \\
& \text{ [y = (value-of-expression} \text{ <<-}(z,3) \text{>> } \rho_1) \rho_1) \\
= \text{(value-of-expression} & \text{ <<-}(x,y),z \text{>>} \\
& \text{ [y = (} \text{ (value-of-expression} \text{ <<-} z \text{>> } \rho_1) \\
& \text{ 3)] } \rho_1) \\
= \text{(value-of-expression} & \text{ <<-}(x,y),z \text{>>} \\
& \text{ [y = (} \text{ (- (value-of-expression} \text{ <<-} \rho_1) \\
& \text{ 3)] } \rho_1) \\
= \text{(value-of-expression} & \text{ <<-}(x,y),z \text{>>} \\
& \text{ [y = (} \text{ (- 7 3)] } \rho_1) \\
= \text{(value-of-expression} & \text{ <<-}(x,y),z \text{>>} \\
& \text{ [y = (} \text{ (- 7 3)] } \rho_1) \\
= \text{(value-of-expression} & \text{ <<-}(x,y),z \text{>>} \\
& \text{ [y = 4] } \rho_1) \\
\text{(Let } \rho_2 = [y = 4] \rho_1 = [y=4,x=5,z=7]) \\
= \text{(value-of-expression} & \text{ <<-}(x,y),z \text{>> } \rho_2)
\end{align*}
\]
= (- (- (value-of-expression <<x>> ρ₂)
     (value-of-expression <<y>> ρ₂))
     (value-of-expression <<z>> ρ₂))

= (- (- 5
     4)
     7)

= (- 1 7)

= -6

OK, this is tedious. Computers are clearly better at this than we are. So let’s implement the specification.
3.1.9 Implementing the Language

We implement the language as a set of PLT Scheme modules.

(module lang ; this is lang.scm
  (lib "eopl.ss" "eopl") ; it is written in the eopl language level

  (require "drscheme-init.scm") ; it imports some stuff for csgll1

  (provide (all-defined)) ; it exports too much stuff to list.

  ;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;

  (define the-lexical-spec
    '((whitespace (whitespace) skip)
      (comment "%" (arbno (not #\newline))) skip)
    (identifier
      (letter (arbno (or letter digit "_" "-" "?")))
      symbol)
    (number (digit (arbno digit)) number)
    (number ("-" digit (arbno digit)) number)
    ))

  (define the-grammar
    '((program (expression) a-program)
      (expression (identifier) var-exp)
      (expression (number) const-exp)
      (expression ("-" "(" expression "," expression ")") diff-exp)
      (expression ("zero?" "(" expression ")") zero?-exp)
      (expression
        ("if" expression "then" expression "else" expression)
        if-exp)
    (expression
      ("let" identifier "=" expression "in" expression)
      let-exp)
    ))

  ;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;

17
(sllgen:make-define-datatypes the-lexical-spec the-grammar)

(define show-the-datatypes
  (lambda () (sllgen:list-define-datatypes the-lexical-spec the-grammar)))

(define scan&parse
  (sllgen:make-string-parser the-lexical-spec the-grammar))

(define just-scan
  (sllgen:make-string-scanner the-lexical-spec the-grammar))

)
This generates the following datatypes:

(define-datatype program program?
  (a-program
   (e expression?)))

(define-datatype expression expression?
  (const-exp
   (n number?))
  (diff-exp
   (exp1 expression?)
   (exp2 expression?))
  (zero?-exp
   (exp1 expression?))
  (if-exp
   (exp1 expression?)
   (exp2 expression?)
   (exp3 expression?))
  (var-exp
   (var symbol?))
  (let-exp
   (var symbol?)
   (rhs-exp expression?)
   (body expression?)))
The next module is for data structures: for expressed values, also environments. Later on, these will be mutually recursive, so they will need to go in the same module.

(module data-structures (lib "eopl.ss" "eopl")

  (require "lang.scm") ; for expression?
  (provide (all-defined)) ; too many things to list

;;; expressed values ;;;;;;

;;; an expressed value is either a number or a boolean

(define-datatype expval expval?
  (num-val
   (value number?))
  (bool-val
   (boolean boolean?)))

;;; extractors:

(define expval->num
  (lambda (v)
    (cases expval v
      (num-val (num) num)
      (else (expval-extractor-error 'num v)))))

(define expval->bool
  (lambda (v)
    (cases expval v
      (bool-val (bool) bool)
      (else (expval-extractor-error 'bool v)))))

(define expval-extractor-error
  (lambda (variant value)
    (eopl:error 'expval-extractors "Looking for a ~s, found ~s" variant value))))
;;; data structures for environments ;;;;

;;; example of a data type built without define-datatype

(define empty-env-record
  (lambda ()
    '()))

(define extended-env-record
  (lambda (sym val saved-env)
    (cons (list sym val) saved-env)))

(define empty-env-record? null?)

(define environment?
  (lambda (x)
    (or (empty-env-record? x)
      (and (pair? x)
        (symbol? (car (car x)))
        (expval? (cadr (car x)))
        (environment? (cdr x))))))

(define extended-env-record->sym (lambda (r) (car (car r))))

(define extended-env-record->val (lambda (r) (cadr (car r))))

(define extended-env-record->saved-env (lambda (r) (cdr r))))
We put the code for the environment interface in a separate module.

(module environments (lib "eopl.ss" "eopl")

(require "data-structures.scm")
(provide init-env empty-env extend-env apply-env)

;;;;;;; initial environment ;;;;;;;;

;; init-env : () -> environment

;; (init-env) builds an environment in which i is bound to the
;; expressed value 1, v is bound to the expressed value 5, and x is
;; bound to the expressed value 10.

(define init-env
  (lambda ()
    (extend-env
      'i (num-val 1)
      (extend-env
       'v (num-val 5)
       (extend-env
        'x (num-val 10)
        (empty-env))))))

22
(define empty-env
  (lambda ()
    (empty-env-record)))

(define empty-env?
  (lambda (x)
    (empty-env-record? x)))

(define extend-env
  (lambda (sym val Saved-env)
    (extended-env-record sym val Saved-env)))

(define apply-env
  (lambda (env search-sym)
    (if (empty-env? env)
      (eopl:error 'apply-env "No binding for ~s" search-sym)
      (let ((sym (extended-env-record->sym env))
            (val (extended-env-record->val env))
            (Saved-env (extended-env-record->Saved-env env))
            (if (eqv? search-sym sym)
                val
                (apply-env Saved-env search-sym)))))))
Now we get to the interpreter proper:

(module interp (lib "eopl.ss" "eopl")

(require "drscheme-init.scm")

(require "lang.scm")
(require "data-structures.scm")
(require "environments.scm")

(provide value-of-program value-of)

;; the interpreter ;;

;; value-of-program : program -> expval

(define value-of-program
  (lambda (pgm)
    (cases program pgm
      (a-program (body)
        (value-of body (init-env))))))
;;; value-of : expression * environment -> expval

(define value-of
  (lambda (exp env)
    (cases expression exp
      (const-exp (num) (num-val num))
      (var-exp (var) (apply-env env var))
      (diff-exp (exp1 exp2)
        (let ((val1
               (expval->num
                 (value-of exp1 env)))
             (val2
             (expval->num
               (value-of exp2 env)))
               (num-val
                (- val1 val2)))
          (value-of e1 ρ) = v
          (value-of (zero?-exp e1) ρ)
          = \begin{cases} 
            \text{bool-val #t} & \text{if (expval->num v) = 0} \\
            \text{bool-val #f} & \text{if (expval->num v) \neq 0} 
          \end{cases}
        (zero?-exp (exp1)
          (let ((val1 (expval->num (value-of exp1 env)))
             (if (zero? val1)
              (bool-val #t)
              (bool-val #f))))))

25
\[
(value-of \ e_1 \ \rho) = v
\]

\[
(value-of \ (if-exp \ e_1 \ e_2 \ e_3) \ \rho)
= \begin{cases} 
(value-of \ e_2 \ \rho) & \text{if } (expval->bool \ v) = \#t \\
(value-of \ e_3 \ \rho) & \text{if } (expval->bool \ v) = \#f
\end{cases}
\]

(if-exp (exp1 exp2 exp3)
  (if (expval->bool (value-of exp1 env))
    (value-of exp2 env)
    (value-of exp3 env)))

\[
(value-of \ e_1 \ \rho) = v_1
\]

\[
(value-of \ (let-exp \ var \ e_1 \ e_2) \ \rho) = (value-of \ e_2 \ [var = v_1]\rho)
\]

(let-exp (var rhs-exp body)
  (let ((rhs-val (value-of rhs-exp env)))
    (value-of body
      (extend-env var rhs-val env))))

))

)
3.1.10 Testing

A good test plan is important! One of the tenets of agile programming is test-driven programming:

- Build in support for unit tests from the beginning. We’ve done that for you, in drschemainit.scm.
- Design the tests before you design the program.

We start with a test suite:

(module tests mzscheme ; could have put eopl language here

(provide test-list)

(tests)

(define test-list
  '(;

    ;; simple arithmetic
    (positive-const "11" 11)
    (negative-const "-33" -33)
    (simple-arith-1 "-(44,33)" 11)

    ;; nested arithmetic
    (nested-arith-left "-(44,33),22" -11)
    (nested-arith-right "-(55, -(22,11))" 44)

    ;; simple variables
    (test-var-1 "x" 10)
    (test-var-2 "-(x,1)" 9)
    (test-var-3 "-(1,x)" -9)

    ;; simple unbound variables
    (test-unbound-var-1 "foo" error)
    (test-unbound-var-2 "-(x,foo)" error)

    ;; simple conditionals
    (if-true "if zero?(0) then 3 else 4" 3)
(if-true "if (zero? 1) then 3 else 4" 4)

;; test dynamic type checking
(no-bool-to-diff-1 "-(zero? 0),1" error)
(no-bool-to-diff-2 "-(1,zero? 0))" error)
(no-int-to-if "if 1 then 2 else 3" error)

;; make sure that the test and both arms get evaluated
;; properly.
(if-eval-test-true "if zero?(-(11,11)) then 3 else 4" 3)
(if-eval-test-true-1 "if zero?(-(11,11)) then 3 else foo" 3)
(if-eval-test-true-2 "if zero?(-(11,11)) then 3 else 4" 4)

;; and make sure the other arm doesn’t get evaluated.
(if-eval-test-true-2 "if zero?(-(11, 11)) then 3 else foo" 3)
(if-eval-test-true-2 "if zero?(-(11,12)) then foo else 4" 4)

;; simple let
(simple-let-1 "let x = 3 in x" 3)

;; make sure the body and rhs get evaluated
(eval-let-body "let x = 3 in -(x,1)" 2)
(eval-let-rhs "let x = -(4,1) in -(x,1)" 2)

;; check nested let and shadowing
(simple-nested-let "let x = 3 in let y = 4 in -(x,y)" -1)
(check-shadowing-in-body "let x = 3 in let x = 4 in x" 4)
(check-shadowing-in-rhs "let x = 3 in let x = -(x,1) in x" 2)

})
Now let’s put it all together

(module top (lib "eopl.ss" "eopl")

;; top level module. Loads all required pieces and runs the test
;; suite.

(require "drscheme-init.scm")
(require "data-structures.scm") ; for expval constructors
(require "lang.scm") ; for scan&parse
(require "interp.scm") ; for value-of-program
(require "tests.scm") ; for test-list

;; used only at top level, so it doesn’t provide anything.

;;;;;;;;; interface to test harness ;;;;;;;;

;; run : string -> expval

(define run
  (lambda (string)
    (value-of-program (scan&parse string))))

;; run-all : () -> unspecified

;; runs all the tests in test-list, comparing the results with
;; equal-answer?

(define run-all
  (lambda ()
    (run-tests! run equal-answer? test-list)))
(define equal-answer?
  (lambda (ans correct-ans)
    (equal? ans (sloppy->expval correct-ans)))))

(define sloppy->expval
  (lambda (sloppy-val)
    (cond
      ((number? sloppy-val) (num-val sloppy-val))
      ((boolean? sloppy-val) (bool-val sloppy-val))
      (else
       (sopl:error 'sloppy->expval
                      "Can’t convert sloppy value to expval: " s sloppy-val))))))

(run-all)
)

We run the tests by executing `top.scm` in the module language, which puts us inside the module and evaluates `(run-all)`.

no bugs found
In `top.scm` we used `run-tests!`. This procedure comes from `drscheme-init.scm` and has the following specification:

```
;; usage: (run-tests! run-fn equal-answer? tests)

;; run-tests!: (arg -> outcome) * (any * any -> bool) * (list-of test)
;;                -> unspecified

;; where:
;; test ::= (name arg outcome)
;; outcome ::= ERROR | any

;; for each item in tests, apply run-fn to the arg. Check to see if
;; the outcome is right, comparing values using equal-answer?.

;; print a log of the tests.

;; at the end, print either "no bugs found" or the list of tests
;; failed.

;; Normally, run-tests! will recover from any error and continue to
;; the end of the test suite. This behavior can be altered by
;; setting (stop-after-first-error #t).
```
3.2 PROC: A Language with Procedures

Now it’s time to move on to a language with procedures. We will follow the design of Scheme, and let procedures be expressed values in our language, so that

\[
\text{ExpVal} = \text{Int} + \text{Bool} + \text{Proc}
\]

\[
\text{DenVal} = \text{Int} + \text{Bool} + \text{Proc}
\]

where \( \text{Proc} \) is a set of values representing procedures. We will think of \( \text{Proc} \) as an abstract data type. We consider its interface and specification below.

We will also need syntax for procedure creation and calling. This is given by the productions

\[
\text{Expression} ::= \text{proc} \ (\text{Identifier}) \ \text{Expression} \\
\text{proc-exp} \ (\text{var} \ \text{body})
\]

\[
\text{Expression} ::= (\text{Expression} \ \text{Expression}) \\
\text{call-exp} \ (\text{exp1} \ \text{exp2})
\]

Some vocabulary words:

In \( (\text{proc-exp} \ \text{var} \ e) \), the identifier \( \text{var} \) is the bound variable or formal parameter and \( e \) is the body. In a procedure call \( (\text{call-exp} \ e_1 \ e_2) \), the expression \( e_1 \) is the operator and \( e_2 \) is the operand or actual parameter. We use the word argument to refer to the value of an actual parameter.
3.2.1 The datatype Proc

Interface: the constructor \texttt{procedure}, which tells how to build a procedure value, and the observer \texttt{apply-procedure}, which tells how to apply a procedure value. Our next task is to determine what information must be included in a value representing a procedure. To do this, we consider what happens when we write a \texttt{proc} expression in an arbitrary position in our program.

```plaintext
let x = 200
in let f = proc (z) -(z,x) ;; result should be sub200
    in let x = 100
        in let g = proc (z) -(z,x) ;; same exp, but result should
            ;; be sub100
                in -((f 1), (g 1))
```

Two procedures, created from identical expressions, must behave differently. Conclusion: value of a \texttt{proc} expression must depend in some way on the environment in which the expression is evaluated. Therefore the constructor \texttt{procedure} must take three arguments: the bound variable, the body, and the environment, and the specification for a \texttt{proc} expression should be

\[
\text{value-of (proc-exp var e) } \rho = \text{proc-val (procedure var e } \rho))
\]

where \texttt{proc-val} is the constructor, like \texttt{bool-val} or \texttt{num-val}, that builds an expressed value from a \texttt{Proc}. 35
At a procedure call, we want to find the value of the operator and the operand. If
the value of the operator is a proc-val, then we want to apply it to the value of
the operand.

\[
\text{(value-of (call-exp } e_1 e_2 \text{) } \rho) \\
= \text{(let } ((v1 (value-of } e_1 \text{ } \rho)) \\
\quad (v2 (value-of } e_2 \text{ } \rho))) \\
\quad \text{(let } ((\text{proc (expval->proc } v1)))) \\
\quad \text{(apply-procedure proc } v2)))
\]
What happens when apply-procedure is invoked?
Lexical scope rule tells us that when a procedure is applied, its body is evaluated in an environment that binds the formal parameter of the procedure to the argument of the call.
Furthermore any other variables must have the same values they had at procedure-creation time.
Therefore these procedures should satisfy the condition

\[
(\text{apply-procedure} \ (\text{procedure} \ \text{var} \ e \ \rho) \ v) \\
= (\text{value-of} \ e \ [\text{var} = v] \rho)
\]
3.2.2 Calculating with this Specification

Let’s do a couple of short examples to show how these things fit together.

Note that this is really a calculation using the specification, not the implementation. Let \( \rho_0 = [x=10] \)

\[
\begin{align*}
(\text{value-of } & \langle\text{let } f = \text{proc}(z)-(z,x) \text{ in } (f \ 21)\rangle \ \rho_0) \\
= (\text{value-of } & \langle(f \ 21)\rangle) \\
& \quad [f = (\text{value-of } \langle\text{proc}(z)-(z,x)\rangle \ \rho_0)] \ \rho_0) \\
= (\text{value-of } & \langle(f \ 21)\rangle) \\
& \quad [f = (\text{procedure } z \ \langle-(z,x)\rangle \ \rho_0)] \ \rho_0) \\
= (\text{apply-procedure} \\
& \quad (\text{value-of } \langle f \rangle \quad [f = (\text{procedure } z \ \langle-(z,x)\rangle \ \rho_0)] \ \rho_0) \\
& \quad (\text{value-of } \langle 21 \rangle \quad [f = (\text{procedure } z \ \langle-(z,x)\rangle \ \rho_0)] \ \rho_0)) \\
= (\text{apply-procedure} \\
& \quad (\text{procedure } z \ \langle-(z,x)\rangle \ \rho_0) \\
& \quad 21) \\
= (\text{value-of } \langle-(z,x)\rangle \quad [z=21]\ \rho_0) \\
= (- \ (\text{value-of } \langle z \rangle \quad [z=21]\ \rho_0) \\
& \quad (\text{value-of } \langle x \rangle \quad [z=21]\ \rho_0)) \\
= (- \ 21 \ 10) \\
= 11
\end{align*}
\]

Exercise: try the same thing for

\[
\begin{align*}
\text{let } f &= \text{proc } (x) \ \text{proc}(y) \ -(x,y) \\
\text{in let } g &= (f \ 55) \\
& \quad \text{in } (g \ 33)
\end{align*}
\]
Now let’s try the same example, except let’s name the procedure \(x\):

\[
(value-of \langle\langle let \ x = proc(z)-(z,x) in \ (x \ 21)\rangle\rangle \ \rho_0)
\]

\[
= (value-of \langle\langle x \ 21\rangle\rangle
\quad [x = (value-of \langle\langle proc(z)-(z,x)\rangle\rangle \ \rho_0)] \rho_0)
\]

\[
= (value-of \langle\langle x \ 21\rangle\rangle
\quad [x = (procedure z \langle-(z,x)\rangle \ \rho_0)] \rho_0)
\]

\[
= (apply-procedure
\quad (value-of \langle\langle\rangle\rangle \quad [x = (procedure z \langle-(z,x)\rangle \ \rho_0)] \rho_0)
\quad (value-of \langle21\rangle \quad [x = (procedure z \langle-(z,x)\rangle \ \rho_0)] \rho_0))
\]

\[
= (apply-procedure
\quad (procedure z \langle-(z,x)\rangle \ \rho_0)
\quad 21)
\]

\[
= (value-of \langle-(z,x)\rangle \ [z=21] \rho_0)
\]

\[
= (- (value-of \langle\langle z\rangle\ [z=21] \rho_0)
\quad (value-of \langle\langle x\rangle\ [z=21] \rho_0))
\]

\[
= (- 21 \ 10) \quad ; \ x \ is \ still \ bound \ to \ 10!
\]

\[
= 11
\]
3.2.3 Representing Procedures

Must define apply-procedure and procedure so that

\[
(\text{apply-procedure} \ (\text{procedure} \ \text{var} \ e \ \rho) \ v) \\
= (\text{value-of} \ e \ (\text{extend-env} \ \text{var} \ v \ \rho))
\]

Usual representation is as a data structure:

```scheme
(proc? : Scheme value -> boolean
procedure : vble * expression * env -> proc
;; This must be in data-structures.scm, since procedures, expvals, 
;; and environments are mutually recursive.
(define-datatype proc proc?
  (procedure
   (var symbol?)
   (body expression?)
   (env environment?)))

apply-procedure : proc * expval -> expval
;; This must be in interp.scm, since apply-procedure and
;; value-of are mutually recursive.
(define apply-procedure
  (lambda (proc1 val)
    (cases proc proc1
      (procedure (var body saved-env)
        (value-of body (extend-env var val saved-env)))))))
```

These data structures are often called closures, because they are self-contained: they contain everything the procedure needs in order to be applied. We sometimes say the procedure is closed over or closed in its creation environment.

This representation is in proc-lang/ds-rep
Alternatively, we can represent a procedure by its action under apply-procedure:

```scheme
proc? : Scheme-value -> boolean
(define proc?
    (lambda (v)
        (procedure? v)))

procedure : vble * expression * env -> proc
;; This must be in interp.scm, since procedure and value-of
;; are mutually recursive.
(define procedure
    (lambda (x e saved-env)
        (lambda (v)
            (value-of e (extend-env x v saved-env)))))

apply-procedure : procedure * expval -> expval
;; in interp.scm
(define apply-procedure
    (lambda (proc v)
        (proc v)))
```

The function proc?, as defined here, is somewhat inaccurate, since not every Scheme procedure is a possible procedure in our language. We need it only for defining the datatype expval.

This is is at proc-lang/proc-rep.
In either case we need to add an alternative to the datatype \texttt{expval}

\begin{verbatim}
(define-datatype expval expval?
  (num-val
   (value number?))
  (bool-val
   (boolean boolean?))
  (proc-val
   (proc proc?)))
\end{verbatim}

and we need to add two new clauses to \texttt{value-of}

\begin{verbatim}
  (proc-exp (var body)
    (proc-val (procedure var body env)))

  (call-exp (exp1 exp2)
    (let ((v1 (value-of exp1 env))
          (v2 (value-of exp2 env))
          (let ((proc (expval->proc v1)))
            (apply-procedure proc v2))))
\end{verbatim}

And we're done!
And of course we have to add some tests:

;;; in tests.scm:

;;; simple applications
(apply-proc-in-rator-pos "(proc(x) -(x,1) 30)" 29)
(apply-simple-proc "let f = proc (x) -(x,1) in (f 30)" 29)
(let-to-proc-1 "(proc(f)(f 30) proc(x)-(x,1))" 29)

(nested-procs "((proc (x) proc (y) -(x,y) 5) 6)" -1)
(nested-procs2 "let f = proc(x) proc (y) -(x,y) in ((f -(10,5)) 6)"
 -1)

(y-combinator-1 "
let fix = proc (f)
    let d = proc (x) proc (z) ((f (x x)) z)
    in proc (n) ((f (d d)) n)
in let
    t4m = proc (f) proc(x) if zero?(x) then 0 else -((f -(x,1)),-4)
in let times4 = (fix t4m)
in (times4 3)"
  12)
3.3 LETREC: A language with recursive procedures

We now define a new language LETREC, which adds recursion to our language. Since our language has only 1-argument procedures, we make our life simpler by having our letrec’s declare only a single 1-argument procedure, for example

```scheme
letrec double(x) = if zero?(x)
    then 0
    else -((double -(x,1)), -2)
  in (double 6)
```

The left-hand side of a recursive declaration is the name of the recursive procedure and its bound variable. Procedure body is to the right of the =.

\[
Expression ::= \text{letrec } \text{Identifier } (\text{Identifier}) = \text{Expression} \text{ in Expression} \\
\text{letrec-exp } (\text{proc-name bound-var proc-body letrec-body})
\]

The value of a letrec expression is the value of the body in an environment that has the desired behavior:

\[
(value-of (letrec-exp pname var e_1 e_2) \rho) \\
= (value-of e_2 (extend-env-recursively pname var e_1 \rho))
\]

To implement this, just need to add one line to `value-of`. 
We add a new procedure `extend-env-recursively` to the environment interface.

We specify the behavior of this environment as follows: Let $\rho_1$ be the environment produced by `(extend-env-recursively pname var_1 e_1 \rho)`. Then what should `(apply-env \rho_1 var_2)` return?

1. If the variable $var_2$ is the same as `pname`, then `(apply-env \rho_1 var_2)` should produce a closure whose bound variable is `var_1`, whose body is `e_1`, and with an environment in which $p$ is bound to this procedure. But we already have such an environment, namely $\rho_1$ itself! So

   $$(\text{apply-env } \rho_1 \text{ pname}) = (\text{procedure } var_1 e_1 \rho_1)$$

2. If $var_2$ is not the same as `pname`, then

   $$(\text{apply-env } \rho_1 \text{ var}_2) = (\text{apply-env } \rho \text{ var}_2)$$

Let’s do an example.

```scheme
(value-of <!letrec double(x) = if zero?(x) then 0 else -((double -(x,1)), -2) in (double 6) >> \rho_0)
```

= `(value-of <!((double 6) >> (extend-env-recursively double x <!if zero?(x) ... >> \rho_0))`
= (apply-procedure
  (value-of <<double>> (extend-env-recursively double x
    <<if zero?(x) ...>> \rho_0))
  (value-of <<6>> (extend-env-recursively double x
    <<if zero?(x) ...>> \rho_0)))

= (apply-procedure
  (procedure x <<if zero?(x) ...>>
    (extend-env-recursively double x <<if zero?(x) ...>> \rho_0))
  6)

= (value-of <<if zero?(x) ...>> [x=6](extend-env-recursively double x
    <<if zero?(x) ...>> \rho_0))

...
We can implement `extend-env-recursive` in any way that satisfies these requirements.

In an abstract-syntax representation, add a new variant, and then make `apply-env` do the right thing.

```scheme
;; in data-structures.scm
(define-datatype environment environment?
  (empty-env)
  (extend-env
   (var symbol?)
   (val expval?)
   (saved-env environment?))
  (extend-env-recursively
   (proc-name symbol?)
   (bound-var symbol?)
   (proc-body expression?)
   (saved-env environment?)))

;; in environments.scm
(define apply-env
  (lambda (env search-sym)
    (cases environment env
      (empty-env ()
        (eopl: error 'apply-env
          "No binding for " s" search-sym))
      (extend-env (var val saved-env)
        (if (eqv? search-sym var)
          val
          (apply-env saved-env search-sym))
        (extend-env-recursively (proc-name bound-var proc-body saved-env)
          (if (eqv? search-sym proc-name)
            (proc-val (procedure bound-var proc-body env))
            (apply-env saved-env search-sym))))))
```

The `env` on the next-to-last line corresponds to $\rho_1$ in the discussion above.
3.4 Simulating letrec

We don’t really need a letrec primitive: in our language, we can do this already: consider the following bit of code:

```scheme
let fix = proc (f)
    let d = proc (x) proc (z) (f (x x) z)
    in proc (n) (f (d d) n)
  t4m = proc (f) proc (x) if x then +(4, (f -(x,1))) else 0
in let times4 = (fix t4m)
    in (times4 3)
```

Then we have

\[
\text{(times4 3)} \\
= \text{(fix t4m) 3)} \\
= \text{((t4m (d d)) 3)} \quad ; \quad d = \text{proc (x) proc (z) ((t4m (x x)) z)}, \\
= +(4, ((d d) 2)) \quad ; \quad \text{so ((d x) z) = ((t4m (x x)) z)} \\
= +(4, (t4m (d d) 2)) \quad ; \quad \text{ahh- we had ((t4m (d d)) 3) before-- so we've recurred!} \\
= +(4, +(4, ((d d) 1))) \\
\text{etc.} \\
= +(4, +(4, +(4, ((t4m (d d)) 0)))) \\
= +(4, +(4, +(4, 0))) \\
= 12
\]

See Chapter 9 of the Little Schemer for more discussion.

[Puzzle: What is the justification for using equational reasoning here?]
3.5 Multiple Arguments and Declarations

LETREC illustrated most of the important features of programming languages that we will study. But it’s still somewhat primitive. To get a somewhat more realistic language, we need to add more primitives (possibly of several arguments), procedures of several arguments, and declarations of multiple variables.

We’d like to write things like

```
let z = 5
    x = 3
in let x = 4
    y = +(x,z)  % here x = 3
    in *(z, +(x,y))  % here x = 4
```

and

```
letrec
    even(x) = if zero?(x) then 1 else (odd -(x,1))
    odd(x)  = if zero?(x) then 0 else (even -(x,1))
    prod(x,y) = if zero?(x) then 0 else +(x, (prod -(x,1) y))
in (odd 13)
```

This requires almost no new ideas, but a little more engineering. We’ll just go over the differences. (Sorry, this isn’t in the repository as of right now.)

;; In lang.scm:

```
(define the-grammar
  '(((program (expression) a-program)

  ...

  ;; application of a primitive
  (expression
    (primitive "(" (separated-list expression ",") "))
  primcall-exp)
```

49
;; allow many declarations in a let
(expression
  ("let" (arbno identifier "=" expression) "in" expression)
  let-exp)

;; allow many bound variables in a procedure
(expression
  ("proc" "(" (separated-list identifier ",") ")" expression)
  proc-exp)

;; allow many operands in a procedure call
(expression
  ("(" expression (arbno expression) ")")
  call-exp)

;; allow many declarations of n-ary procedures in a letrec
(expression
  "letrec"
  (arbno identifier "(" (separated-list identifier ",") ")"
   "=" expression)
  "in" expression)
  letrec-exp)

;; primitives
(primitive ("+")) add-prim
(primitive ("-")) subtract-prim
(primitive ("*")) mult-prim
(primitive ("add1") incr-prim)
(primitive ("sub1") decr-prim)
(primitive ("zero?") zero-test-prim)
3.5.1 Specification

This will be much like the specification of 1-argument procedures, only with more arguments:

\[
\begin{align*}
\text{value-of} \ (\text{proc-exp} \ (var_1 \ldots \ var_n) \ e) \ \rho & = (\text{proc-val} \ (\text{procedure} \ (var_1 \ldots \ var_n) \ e) \ \rho) \\
\text{value-of} \ (\text{call-exp} \ rator \ \text{rands}) \ \rho & = (\text{let} \ ((\text{rator-val} \ (\text{value-of} \ rator) \ \rho) \\
& \quad (\text{rand-vals} \ (\text{values-of} \ \text{rands} \ \rho))) \\
& \quad (\text{let} \ ((\text{proc} \ (\text{expval->proc} \ \text{rorator-val}))) \\
& \quad (\text{apply-procedure} \ \text{proc} \ \text{rand-vals}))) \\
\text{values-of} \ (e_1 \ldots e_n) \ \rho & = (\text{list} \ \text{value-of} \ e_1 \ \rho) \ldots \ (\text{value-of} \ e_n \ \rho) \\
\text{apply-procedure} \ (\text{procedure} \ (var_1 \ldots var_n) \ e) \ \rho \ (v_1 \ldots v_n) & = \ \text{value-of} \ e \ [\text{var}_1=\text{v}_1, \ldots \ \text{var}_n=\text{v}_n] \ \rho
\end{align*}
\]

Also need to modify \texttt{extend-env} so that it takes a list of variables and a list of values and zips them into an environment, as indicated in the last equation above.
In interp.scm:

;; value-of : expression * environment -> expval
(define value-of
  (lambda (exp env)
    (cases expression exp

    ;; new
    (primcall-exp (prim rands)
      (let ((args (values-of rands env)))
        (apply-primitive prim args))

    ;; changed
    (let-exp (vars rhs-exps body)
      (let ((vals (values-of rhs-exps env))
        (value-of body
          (extend-env* vars vals env)))

    ;; bvar -> bvars
    (proc-exp (bvars body) (procedure bvars body env))

    ;; rand -> rands
    (call-exp (rator rands)
      (let ((rator-val (value-of rator env))
        (rand-vars (values-of rands env)))
        (let ((proc (expval->proc rator-val)))
          (apply-procedure proc rand-vars))

    ;; proc-name -> proc-names, etc.
    (letrec-exp (proc-names bound-vars proc-bodies letrec-body)
      (value-of letrec-body
        (extend-env-recursively proc-names bound-vars proc-bodies env)))

))))
;; values-of-expressions : (list-of expression) * environment
-> (list-of expval)
(define values-of
 (lambda (expss env)
   (map
    (lambda (exp) (value-of exp env))
    expss)))

(define apply-procedure
 (lambda (proc args)
   (cases procval proc
    (closure (vars body env)
      (value-of body
       (extend-env vars args env))))))

We need to add apply-primitive.scm (which we require in interp.scm):

(module apply-primitive (lib "eopl.ss" "eopl")

(require "lang.scm")

(provide apply-primitive)

(define apply-primitive
 (lambda (prim args)
   (cases primitive prim
    (subtract-prim ()
     (let ((val1 (expval->num (car args)))
         (val2 (expval->num (cadr args))))
       (num-val (- val1 val2)))
       ...)))

)
;; in data-structures.scm

(define-datatype environment environment?
  (empty-env)
  (extend-env
    (vars (list-of symbol?))
    (vals (list-of expval?))
    (saved-env environment?))

(define-datatype proc proc?
  (procedure
    (vars (list-of symbol?))
    (body expression?)
    (saved-env environment?)))
;; in environments.scm

(define apply-env
  (lambda (env search-sym)
    (cases environment env
      (empty-env ()
        (eopl:error 'apply-env
          "No binding for ~s" search-sym))
      (extend-env (vars vals saved-env)
        (let ((maybe-pos (find-pos search-sym vars)))
          (if (number? maybe-pos)
            (list-ref vals maybe-pos)
            (apply-env saved-env search-sym))))
      (extend-env-recursively (proc-names bvarss proc-bodies saved-env)
        (let ((maybe-pos (find-pos search-sym proc-names)))
          (if (number? maybe-pos)
            (proc-val
              (procedure
                (list-ref bvarss maybe-pos)
                (list-ref proc-bodies maybe-pos)
                env))
            (apply-env saved-env search-sym))))))

;; find-pos : sym * (listof sym) -> num OR non-number
;; (find-pos sym syms) returns the position of sym in syms,
;; otherwise returns a non-number

;; implementation is left as an exercise (See EDPL3, ex. 1.22).
