Assumption: Assume there exists a probabilistic linear relationship between a subset of plaintext bits and a subset of state bits immediately preceding the last substitution Attacker has a large amount of plaintext-ciphertext encrypted using the same key Principle: Consider a set of potential sub-keys, whenever a sub-key verifies the linear relation, increment its counter The sub-key with highest counter could contain the correct values of key bits

Classical Cryptography

2

Pill	ing-up Lemma	
■ Giv	en:	
	X ₁ , X ₂ , independent random variables	
	$Pr[X_i=0] = p_i$; $Pr[X_i=1] = 1-p_i$; $0 \le p_i \le 1$	
•	Let $\epsilon_i = p_i$ - $1/2$ denote the bias of the distribution	
■ Pilli	ing-up Lemma:	
	Let $\epsilon_{i1,i2,\dots,ik}$ denote the bias of the random variable $X_{i1} \oplus X_{i2} \oplus \dots$	
	$\oplus X_{ik}$. Then: $arepsilon_{i1,i2,,ik} = 2^{k-1} \prod_{j=1}^k arepsilon_{ij}$	
■ Cor	rollary:	
- :	If $\epsilon_{ij} = 0$ for one variable $\Rightarrow \; \epsilon_{i1,i2,,ik} = 0$	
Fall'04: CSG252	Classical Crypthography	_

Lin	ear Approximations of S-boxes	
S-t	OOX:	
	$\Pi_{s}: \{0, 1\}^{m} \to \{0, 1\}^{n}$	
	Input:	
	$X = (x_1,, x_m)$	
	Each coordinate defines a random variable X _i with bias 0	
	 Variables X_is are independent Output: 	
•	$ Y = (y_1,, y_n) $	
	 Variables Y_is are not independent from each other and X_is 	
	• If $(y_1,,y_n) \neq \Pi_S(x_1,,x_m) \Rightarrow \Pr[X_1 = x_1,,X_m = x_m,Y_1 = y_1,,X_m = x_m,Y_1 = y_1,]$,
	• If $(y_1,, y_n) = \Pi_S(x_1,, x_m) \Rightarrow \Pr[X_1 = x_1,, X_m = x_m, Y_1 = y_1,, Y_n = y_n,] = ?$	٠,
•	Therefore: one can compute the bias of: $X_{i1} \oplus \oplus X_{ik} \oplus Y_{j1} \oplus \oplus X_{ik} \oplus Y_{jk} \oplus X_{ik} \oplus X_{$	Y _{jl}
Eall/04: CCC2E2	Classical Counterpoly	

Linear Attack on SPN

Approach:

- Find a set of linear approximations of S-boxes that can be used to derive a linear approximation of the SPN (excluding the last
- Derive the bias value using pilling-up lemma
- This linear approximation depends on some subset of the key
- For each possible pair (plaintext, ciphertext), and each key increment the counter of the subkey if the approximation equation gives a 0
- Hopefully the correct value for sub-keys will have the expected bias

II'04: CSG252

Classical Cryptography

Example

- Approximation equations:

 - T₁ has bias ¼
 T₂ has bias -¼

 - T₃ has bias -1/4
 T₄ has bias -1/4
- $T_3 = U_6^3 \oplus V_6^3 \oplus V_8^3$ $T_4 = U_{14}^3 \oplus V_{14}^3 \oplus V_{16}^3$

 $T_1 = U_5^1 \oplus U_7^1 \oplus U_8^1 \oplus V_6^1$

 $T_2 = U_6^2 \oplus V_6^2 \oplus V_8^2$

- If T₁, T₂, T₃, T₄, were **independent** then the bias of
 T₁⊕ T₂⊕ T₃⊕ T₄ would be -1/32
 We will make this non-rigorous approximations, because it seems to work in practice
- $\begin{array}{lll} \bullet & T_1 \oplus T_2 \oplus T_3 \oplus T_4 = X_5 \oplus X_7 \oplus X_8 \oplus V^3_5 \oplus V^3_5 \oplus V^3_{14} \oplus V^3_{16} \oplus K^1_5 \oplus K^1_7 \\ & \oplus K^1_8 \oplus K^2_5 \oplus K^3_5 \oplus K^3_{14} = X_5 \oplus X_7 \oplus X_8 \oplus U^4_5 \oplus U^4_{16} \oplus U^4_8 \oplus U^4_{16} \oplus U^8_{16} \oplus U^4_{16} \oplus W^8_{16} \oplus W^8_{$

Fall'04: CSG252

Classical Cryptography

Example (Cont.) If the key bits in: • K¹₅ ⊕ K¹₂ ⊕ K²₆ ⊕ K³₆ ⊕ K³₁₄ ⊕ K⁴₆ ⊕ K⁴₈ ⊕ K⁴₁₄ ⊕ K⁴₁₆ are fixed Then the random variable: • X, ⊕ X, ⊕ U³₈ ⊕ U⁴₁₄ ⊕ U⁴₈ ⊕ U⁴₁₆ has bias ±1/32 This allows us to derive 8 bits for last subkey: I his allows us to derive 8 bits for last subkey: • $K_{5(2)}^{S}$ and $K_{5(2)}^{S}$. Outline of alg: • Build a table for all possible 256 values of $K_{5(2)}^{S}$ and $K_{5(4)}^{S}$. • For each (x, y) pair of plaintext and ciphertext; for each candidate subkey: • Obtain the values of $W_{5(2)}^{S}$ and $W_{5(4)}^{S}$ by decrypting Y• Compute $x_{5}^{S} \otimes x_{5} \otimes x_{5}^{S} \otimes x_{5}^{S} \otimes w_{5}^{S} \otimes$ Classical Cryptography II'04: CSG252 Requirements for Linear Cryptanalysis A bias of ε requires: • $T = c\epsilon^{-2}$ pairs of plaintext-ciphertext ■ For the previous example T = 8000 was usually successful \Rightarrow c \approx 8 Fall'04: CSG252 Classical Cryptography Differential Cryptanalysis Similar to Linear Cryptanalysis: Compares the x-or of two inputs to the x-or of the corresponding two outputs: $x' = x \oplus x^*$ and $y' = y \oplus y^*$. Adversary has a large number of chosen plaintext tuples (x, x^*, y, y^*) s.t. x' is fixed fixed Approach: For each candidate key: decrypt y, and y* For each candidate key: compute the values of certain state bits For each candidate key: compute the values of certain state bits If the state bits mach the most likely value for the input x-or then increment the candidate key counter Proposed Encryption Standard (PES) which is the original proposal for the International Data Encryption Standard (IDEA used in PGP) was modified to resist to this kind of attacks GSM A3 algorithm is sensitive to this kind of attacks SIM card secret key can be recoverd => GSM cloning

II'04: CSG252

Today's Block Encryption Algorithms

- Key size:
- Two short => easy to guess
- Block size:
 - Two short easy to build a table by the attacker: (plaintext, ciphertext)
 Reasonable size: 64 bits
- Properties:

 - One-to-one mapping
 Mapping should look random to someone who doesn't have the key
 Efficient to compute/reverse
- Substitution (small chunks) & permutation (long chunks)
 Multiple rounds

all'04: CSG252

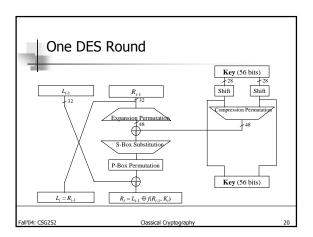

Data Encryption Standard (DES)

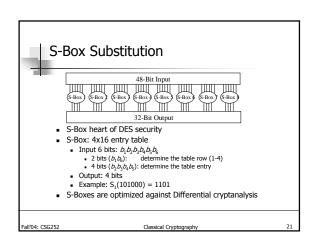

- Developed by IBM for the US government
- Based on Lucifer (64-bits, 128-bits key in 1971)
- To respond to the National Bureau of Standards CFP (now called NIST)
 - Modified characteristics (with help from NSA):
 - 64-bits block size, 56 bits key length
- Concerns about trapdoors, key size, sbox structure
- Adopted in 1977 as the DES (FIPS PUB 46, ANSI X3.92) and reaffirmed in 1994 for 5 more years
- Today replaced by AES

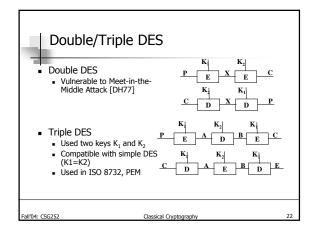

Fall'04: CSG252 Classical Cryptography

Feistel Cipher Function f does not have to be injective! $L_i = R_i - 1$ $R_i = L_i - 1 \oplus f(R_i - 1, K_i)$ How can we invert one round?

DES Linear/Differential Cryptanalysis Differential cryptanalysis • "Rediscovered" by E. Biham & A. Shamir in 1990 Based on a chosen-plaintext attack: Analyse the difference between the ciphertexts of two plaintexts which have a known fixed difference The analysis provides information on the key 8-round DES broken with 2¹⁴ chosen plaintext and complexity 2⁹

- $\,\blacksquare\,\,$ 16-round DES requires $2^{47}\,\text{chosen}$ plaintext and complexity $2^{37}\,$
- DES design took into account this kind of attacks
- Linear cryptanalysis
 - Uses linear approximations of the DES cipher (M. Matsui 1993)
 - Applied to DES:
 - Requires 2⁴³ known plaintext encrypted with the same key
 Time: 40 days to generate the pairs, 10 days to find the key

Fall'04: CSG252 Classical Cryptography

Breaking DES

- Electronic Frontier Foundation built a "DES Cracking Machine" [1998]
 - Attack: brute force
 - Inputs: two ciphertext
 - Architecture:

 - Array of custom chips that can compute DES 24search units/chip x 64chips/board x 27 boards
 - Power:

 - Searches 92 billion keys per second
 Takes 4.5 days for half the key space
 Successfully broke "DES Challenge II-2" in 56 hours
 Takes 4.5 days for half the key space

 - State Cost:
 \$130'000 (all the material: chips, boards, cooling, PC etc.)
 \$80'000 (development from scratch)

	_	

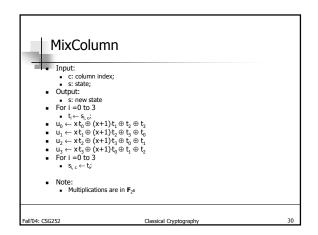

The Advanced Encryption Standard (AES) http://csrc.nist.gov/CryptoToolkit/aes/rijndael/Rijndael.pdf AES = Rijndael Designed by Rijmen-Daemen (Belgium) Key size: 128/192/256 bit Block size: 128 bits of data Properties: iterative rather than Feistel cipher Treats data in 4 groups of 4 bytes Operates on an entire block in every round Designed to be: Resistant against known attacks Speed and code compactness on many CPUs Design simplicity Fall'04: CSG252 Classical Cryptography 25

Implementation Aspects

- Can be efficiently implemented on a 8-bit CPU
 - Byte substitution works on bytes using a table of 256 entries
 - Shift rows is simple byte shifting
 - Add round key works on byte XORs
 - Mix columns requires matrix multiply in F₂8 which works on byte values, can be simplified to use a table lookup

all'na+ rsc252

Classical Cryptography

31

Implementation Aspects

- Can be efficiently implement on 32-bit CPU
 - Redefine steps to use 32-bit words
 - Can pre-compute 4 tables of 256-words
 - Then each column in each round can be computed using 4 table lookups + 4 XORs
 - At a cost of 16Kb to store tables
 - See Problem Set 4.
- Designers believe this very efficient implementation was a key factor in its selection as the AES cipher
