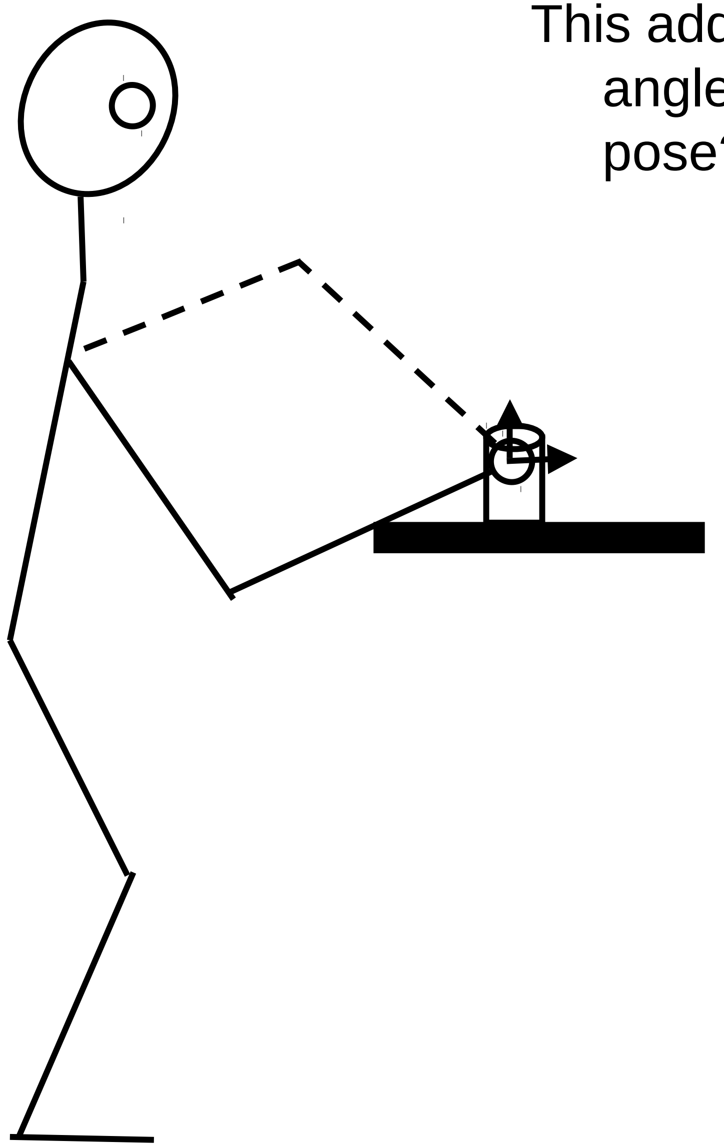
Inverse Kinematics



This addresses the obvious question: what joint angles will place my end effector in a desired pose?

Inverse kinematics

Closed form (analytical) solution: a sequence or set of equations that can be solved for the desired joint angles

- Potentially faster than an iterative solution
- A unique solution to all manipulator positions can be determined *a priori*.
  - Can guarantee “safe” joint configurations where the manipulator does not collide with the body.

Iterative (numerical) solution: numerical iteration toward a desired goal position (variation on Newton’s method)

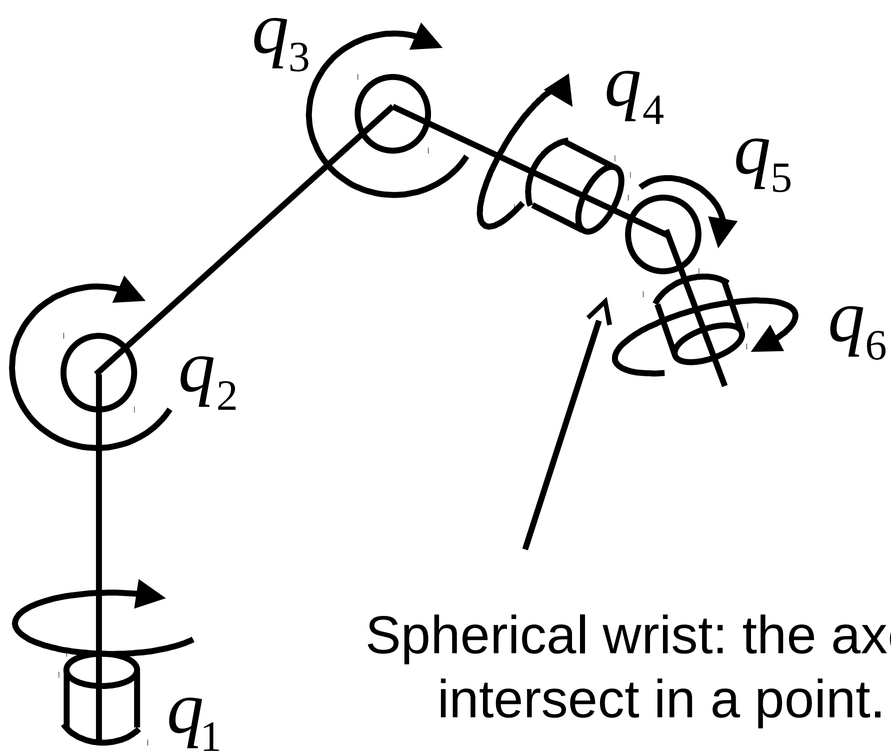
- Easier to think about
- Better suited to incremental displacements and control.

Inverse kinematics

There is no general analytical inverse kinematics solution

- All analytical inverse kinematics solutions are specific to a robot or class of robots.
  - based on geometric intuition about the robot
- I’ll give one example – there are many variations.

Inverse kinematics

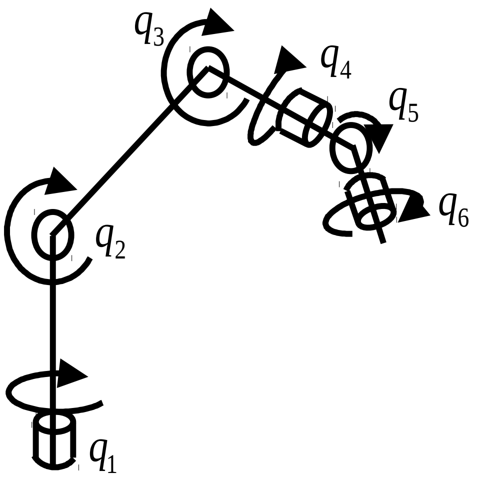


Spherical wrist: the axes of the last three joints intersect in a point.

Consider this 6-joint robot:

- this example is out of the book…

Inverse kinematics



Problem:

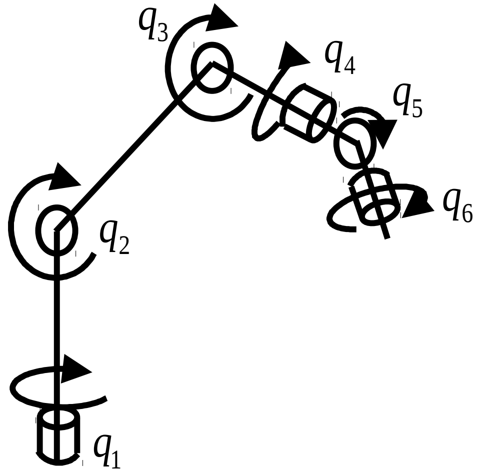
- Given: desired transform, $$T_{eff} = \begin{bmatrix} R_{eff} & d_{eff} \\ 0 & 1 \end{bmatrix}$$

- Find: $$q = \begin{pmatrix} q_1 & q_2 & q_3 & q_4 & \cdots & q_n \end{pmatrix}$$

Note:

- The desired transform (pose) encodes six *degrees of freedom* (this info can be represented by six numbers)
  - Since we only have six joints at our disposal, there is no manifold of *redundant* solutions.
- For this manipulator, the problem can be decomposed into a position component (the first three joints) and an orientation component (the last three joints)
- The first three joints tell you what the position of the spherical wrist

Example: Inverse kinematics



Solution:

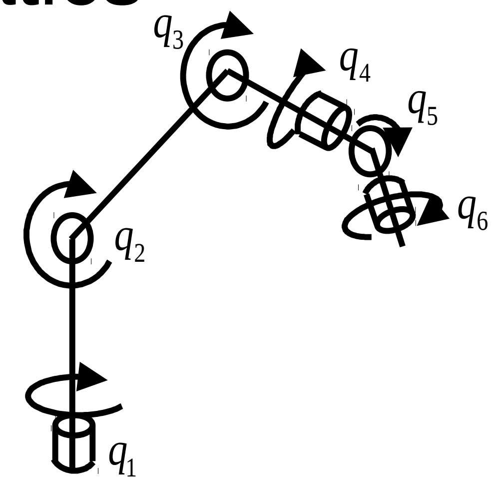
- First, back out the position of the spherical wrist:

Since it's a spherical wrist, the last three joints can be thought of as rotating about a point.

- A constant transform exists that goes from the last wrist joint out to the end effector (sometimes this is called the "tool" transform): ${}^{sw}T_{eff}$

- Back out the position of the wrist: ${}^{b}T_{sw} = {}^{b}T_{eff}\ {}^{sw}T_{eff}^{\ -1}$

Example: Inverse kinematics



- Next, solve for the first three joints

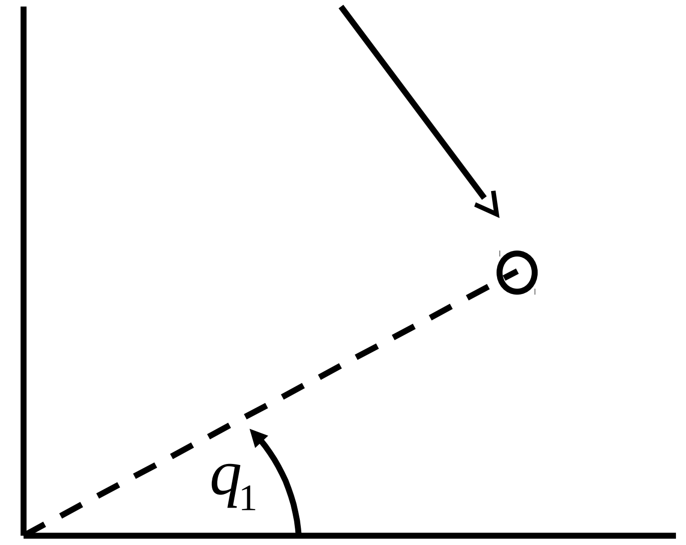
First, solve for q_1. (look down from above)

Goal position in horizontal plane

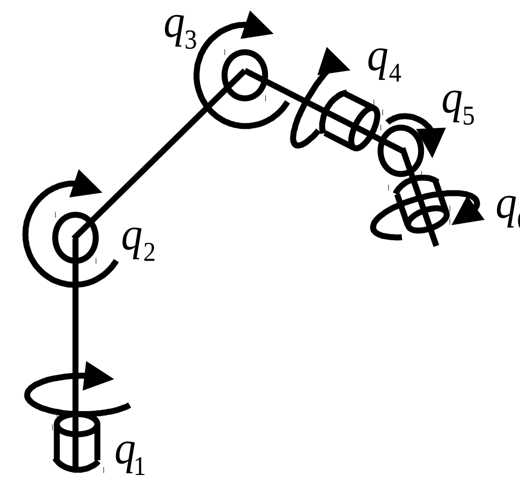
$$q_1 = a\tan 2\left(x_g, y_g\right)$$

or

$$q_1 = a\tan 2\left(x_g, y_g\right) + \pi$$



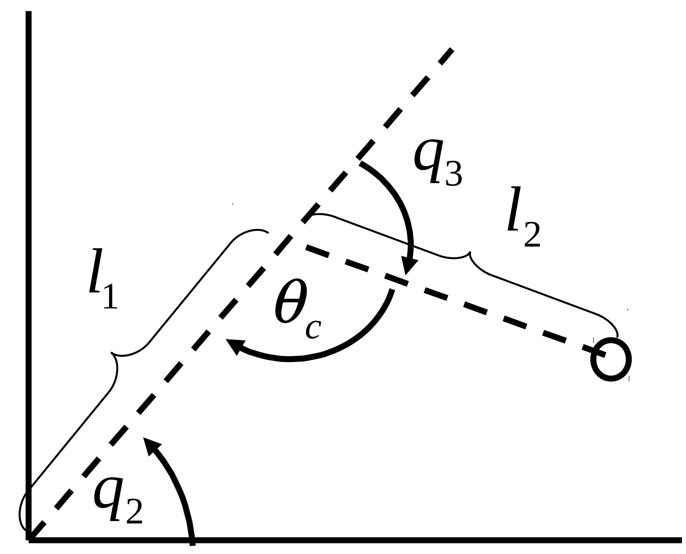
Example: Inverse kinematics



Next, solve for q_3 (look at the manipulator orthogonal to the plane of the first two links)

$$c^2 = a^2 + b^2 - 2ab\cos(\theta_c)$$

$$\cos(\theta_c) = -\frac{r_g^{\ 2} + (z_g - h)^2 - l_1^{\ 2} - l_2^{\ 2}}{2l_1 l_2} = -D$$

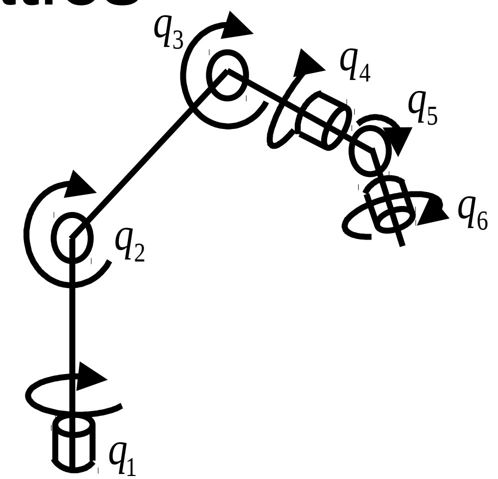


where $r_g^{\ 2} = x_g^{\ 2} + y_g^{\ 2}$

and h is the height of the first link

$$\tan(q_3) = \frac{\pm\sqrt{1 - D^2}}{D}$$

Example: Inverse kinematics

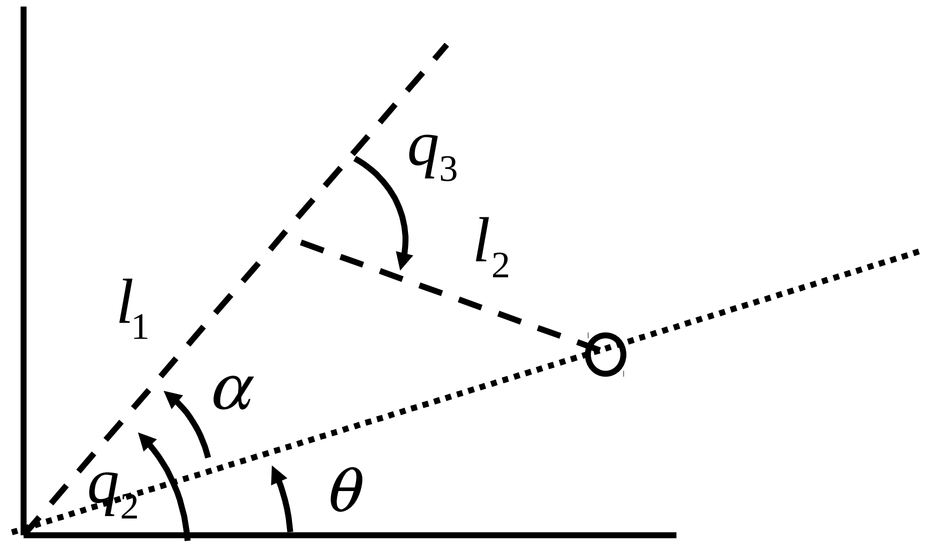


Next, solve for q_2 (continue to look at the manipulator orthogonal to the plane of the first two links)

$$\tan(\theta) = \frac{z_g - h}{\sqrt{x_g^{\,2} + y_g^{\,2}}}$$

$$\tan(\alpha) = \frac{l_2 s_3}{l_1 + l_2 c_3}$$

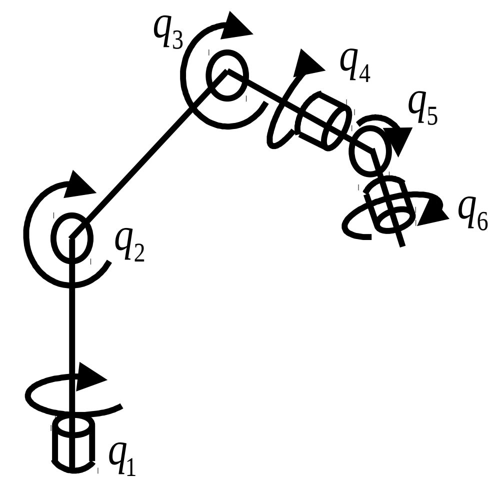
$$q_2 = \theta \pm \alpha$$



Example: Inverse kinematics

Finally, the last three joints completely specify the orientation of the end effector.

- Note that the last three joints look just like ZYZ Euler angles
    - Determination of the joint angles is easy – just calculate the ZYZ Euler angles corresponding to the desired orientation.



Remember: ZYZ Euler Angles

$$R_{zyz}(\phi,\theta,\psi)=\begin{pmatrix}\cos\phi & -\sin\phi & 0\\ \sin\phi & \cos\phi & 0\\ 0 & 0 & 1\end{pmatrix}\begin{pmatrix}\cos\theta & 0 & \sin\theta\\ 0 & 1 & 0\\ -\sin\theta & 0 & \cos\theta\end{pmatrix}\begin{pmatrix}\cos\psi & -\sin\psi & 0\\ \sin\psi & \cos\psi & 0\\ 0 & 0 & 1\end{pmatrix}$$

$$R_{zyz}(\phi,\theta,\psi)=\begin{pmatrix}c_\phi c_\theta c_\psi - s_\phi s_\psi & -c_\phi c_\theta s_\psi - s_\phi c_\psi & c_\phi s_\theta\\ s_\phi c_\theta c_\psi + c_\phi s_\psi & -s_\phi c_\theta s_\psi + c_\phi c_\psi & s_\phi s_\theta\\ -s_\theta c_\psi & s_\theta s_\psi & c_\theta\end{pmatrix}$$

$$\theta = \pm a\tan 2\left(\sqrt{1-r_{33}{}^{2}}, r_{33}\right)$$

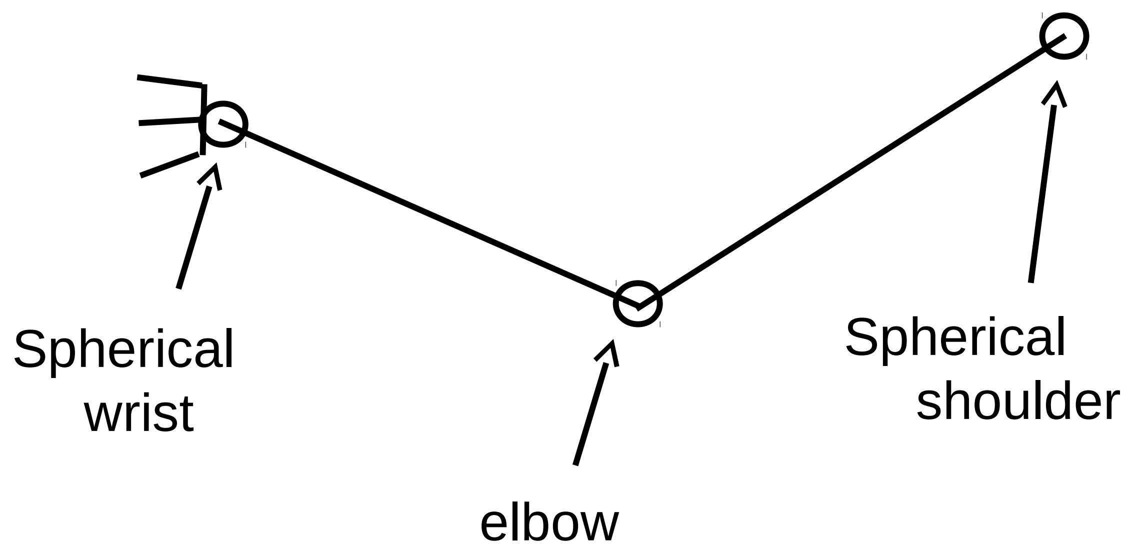
$$\phi = a\tan 2(r_{23}, r_{13}) + k\pi$$

$$\psi = a\tan 2(r_{32}, r_{31})$$

Inverse kinematics for a humanoid arm

You can do similar types of things for a humanoid (7-DOF) arm.

- Since this is a redundant arm, there are a manifold of solutions…



General strategy:

1. Solve for elbow angle
2. Solve for a set of shoulder angles that places the wrist in the right position (note that you have to choose an elbow orbit angle)
3. Solve for the wrist angles
