

13 User Interactions

Goals

In this lab you will learn a little about programming user interactions using the Model-View-Control pattern for organizing the responsibilities.

The JPT library allows you to concentrate on the key concepts and avoid the pitfalls of multitude of details, typically associated with GUI programming.

The Model and the View

The diagram below (on the next page) describes the classes already included in this application:

Here is a brief description of the role these files play in the application.

The model

The program deals with balloons (for now just three of them).

- **class** *Balloon* This class represents one balloon object, allows the user to move it, paint it, and to compare two balloons for closeness to the top of the graphics window.

We could have other classes here, such as a list of balloons, or a list of tied-up balloons and a list fo floating balloons, etc.

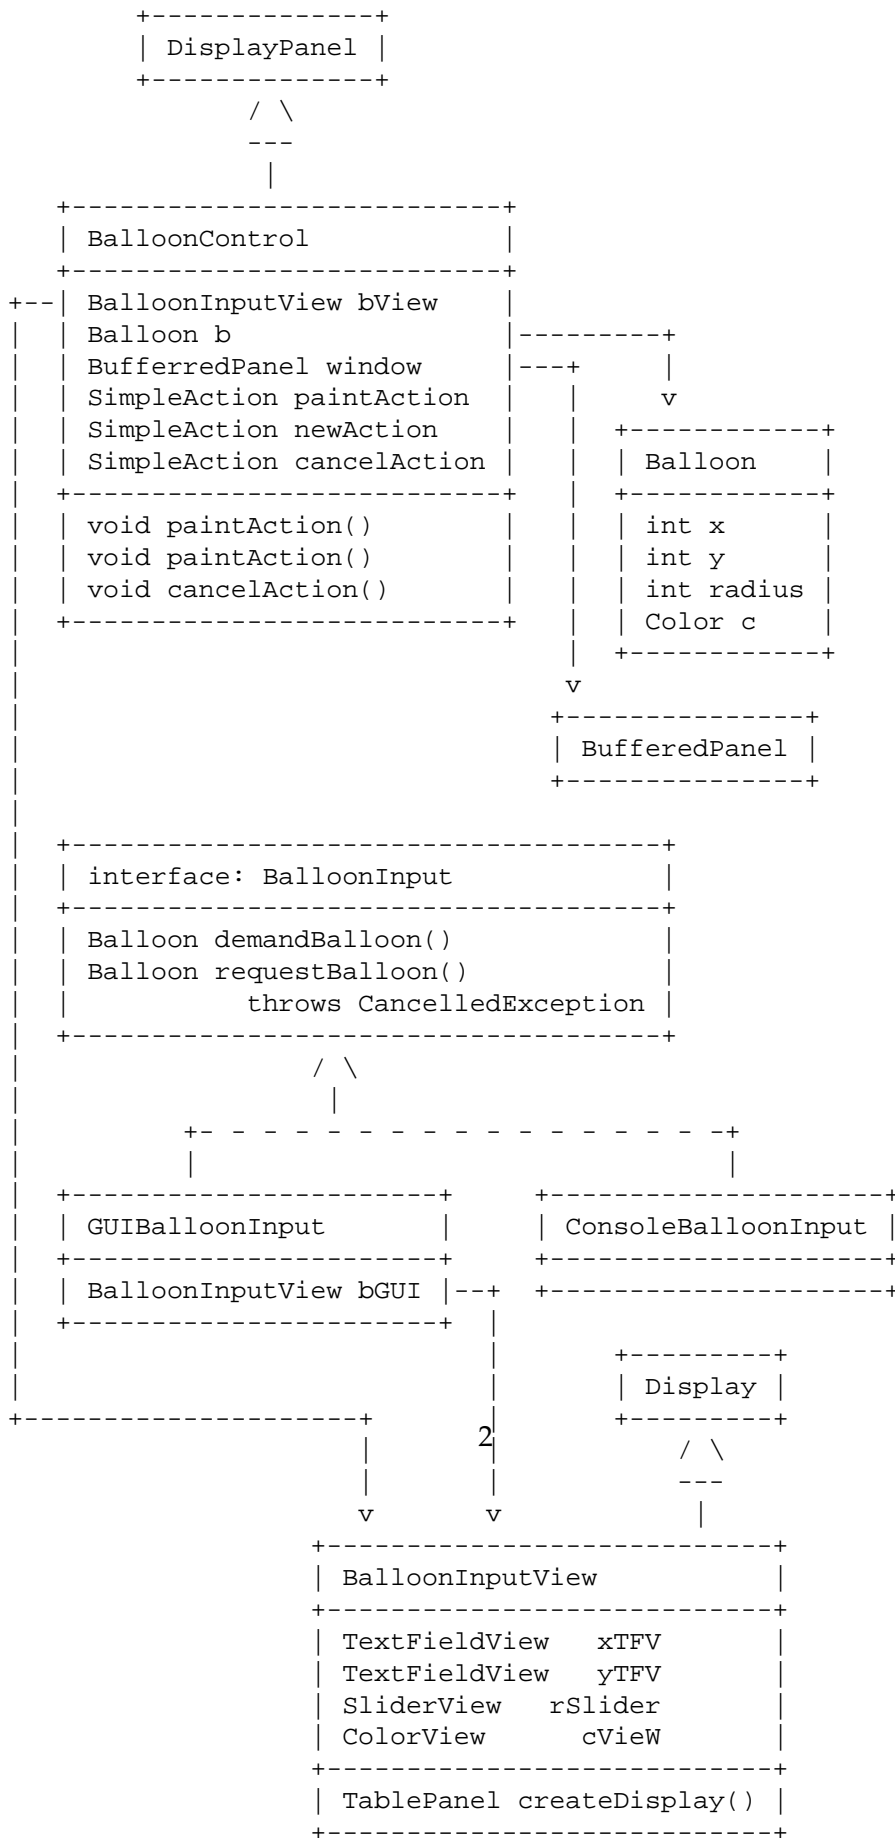

The views

We can view the information about a particular *Balloon* object in several different ways. The *BalloonInput* interface provides two methods for getting the data needed to construct an instance of a new *Balloon*.

To display the information about a *Balloon* object, we can print a String that represents the *Balloon* object in the console, or paint it int the given window, or display the values of its fields in a GUI.

To get the data from the user that is needed to instantiate a new *Balloon* we can read from the console, or from a GUI.

- **interface** *BalloonInput* contains two methods: *demandBalloon()* and *requestBalloon()* that allow us to instantiate a *Balloon* object from the source that implements the methods.

- **class** *ConsoleBalloonInput* implements the *BalloonInput* interface used for reading the input from the console.
- **class** *BalloonInputView* defines a GUI to request the user input for the data needed to initialize one *Balloon* instance. It contains two *TextFieldViews*, one *SliderView*, and one *ColorView*. It also allows us to display the data that represents an instance of a *Balloon*.
- **class** *GUIBalloonInput* implements the *BalloonInput* interface for extracting the user input from the *BalloonInputView* GUI.

The control

- **class** *BalloonControl* adds to the GUI *Actions*. These are buttons that allow the user to choose an action, such as read the *Balloon* data from a GUI and display the *Balloon* in the given canvas. (Our canvas is a window – a buffered panel.)

Run the code, and note the behavior in response to the various buttons.

Getting Familiar with the Environment

1. The model

Read the code for the **class** *Balloon*. Add the method *eraseBalloon* which will paint the balloon in a white color (*Color.white*). Make sure you have the examples and tests for this method.

2. The console input

Read the code for the method *testConsoleInput* in the **class** *Interactions*. Describe to your partner what the method does. Look at the *ConsoleBalloonInput* class and see how the methods *demandBalloon* and *requestBalloon* are implemented. Run the code and see what happens if you type in a wrong data, or when you do not provide any input.

3. The actions

Find the code for the action for the **New** button. Currently, it only sets the value of the *Balloon* instance variables. Add to this action a call to the method which paints the balloon, from the **class** *Balloon*. Make sure it works.

4. Text input from a GUI

Find all places where the *rTFV* is defined or used. It is constructed in the class *BalloonInputView*. This class also defines the methods *demandBalloon* and *requestBalloon*, each of them produces a new instance of a *Balloon* from the user inputs.

In the class *BalloonControl* user input to the *BalloonView* initializes the value of a *Balloon* object that represents our model. We could add to our model a list of tied balloons and a list of floating balloons, and more - for example a child holding the balloon.

DO IT Using a similar technique, define a new *TextFieldView* named *rTFV*, to represent the numerical value of the *Balloon radius*.

5. Connecting slider with a text field

Test the behavior of the slider. Does it have any effect on the balloon? Does it have any effect on the value displayed in the *rTFV* field? Change the value of the *rTFV* field. Does it affect the slider? Does it affect the balloon?

The two views represent the same value and so should be designed to mimic each other. the slider has to act by changing its position whenever a new value is typed into the text field. The value in the text field has to change when the slider is moved, so it reflects its current position.

Define two new *SimpleActions* and the corresponding methods — an *rTFVaction* and a *SliderAction*. It does not matter what you choose for the label, because we are not going to use the actions with a button.

The first one *void rTFVaction* will be invoked when the value in the field *rTFV* changes. It should then set the value of the balloon *radius* and the value of the *rSlider* to the value displayed in the *rTFV*. To set the state of the *rSlider* use the method

```
rSlider.setViewState(" " + b.radius);
```

The second method *void rSliderAction()* will be invoked every time the location of the slider (and the value it represents) changes. It must then change the *radius* of the balloon and set the view state of the *rTFV* calling the method *setViewState* in a manner similar to the above. If you run the program now, you may be surprised to see that these

changes have no effect. Can you think of the way to test that the methods work correctly?

6. Listening to changes in the values

Now you have to tell the *rSlider* and the *rTFV* to perform this action when their values change. The following two statements have to be added at the end of the method *void createViews()*:

```
rTFV.addActionListener(rTFVaction);  
rSlider.addSlidingAction(sliderAction);
```

The first one tells the *rTFV* to perform the *rTFVaction* whenever its value changes. The second one tells the *rSlider* to perform the *sliderAction* whenever the position of the slider (and thus the value it represents) changes.

Test that this works.

7. Reporting changes in the model to the view

Now that you have seen the method *setViewState*, add such method to the **class** *BalloonInputView*. To see that it works, we need to modify some of the fields of a *Balloon* instance and invoke the method. Try it.

8. Adding mouse actions

In the last part you will control the balloon with the mouse. You need to define what should happen when the mouse is clicked (or dragged, or released, etc.). You need to specify which GUI component should listen to the mouse and the user mouse actions. You then need to connect the *MouseListener* with the action it should trigger.

Build a separate frame

The first thing you need to do is to change the manner in which the GUI is displayed. Look at the code in the **class** *Interactions* for the method *testBalloonControl()*. Replace the line which calls the method *showOKDialog* with the following:

```
JPTFrame.createQuickJPTFrame("Balloon Control", bc);
```

This places the *BalloonControl* into a window that runs *in its own thread*, i.e. independently of the rest of the application. That allows

the rest of the application to watch out for the mouse movement and clicks inside of the graphics window.

Define a mouse action The first mouse action you will build will increase the radius of the balloon by ten, every time you click the mouse. All of this is in the **class** *BalloonControl*. Start by defining the method

protected click(MouseEvent mevt) which does the following:

- Print into the console a message that the mouse was clicked.
- Erase the balloon
- Increase the balloon radius by 10
- Set the view state of the *BalloonInputView* *bView* to the current values of the balloon. (Only the radius has changed, but it is easier to let the *BalloonView* do the whole job by invoking the method *setViewState*.
- Finally, paint the changed balloon.

9. Defining and installing Mouse action adapter

Install a *MouseActionAdapter* for the *BufferedPanel* as follows:

- After the definition of the *BufferedPanel*, add the definition:

```
public MouseActionAdapter mouseAdapter;
```

- Inside of the constructor for the **class** *BalloonControl* first initialize the *mouseAdapter* as follows:

```
mouseAdapter = window.getMouseActionAdapter();
```

- Add the action to perform when the mouse is clicked as follows:

```
// respond to mouse clicks
mouseAdapter.addMouseListener(
    new MouseAction() {
        public void mouseActionPerformed(MouseEvent mevt){
            click(mevt);
        }
    });
```

At this point you should test that your program runs as you expected.

10. Tracking the mouse movement

Finally, you will make the balloon move when the mouse moves. Do all the steps you have done for the clicked action, but do not get a new *mouseAdapter*. The following code will add the action:

```
// track mouse motions
mouseAdapter.addMouseMovedAction(
    new MouseAction() {
        public void mouseActionPerformed(MouseEvent mevt){
            track(mevt);
        }
    });
```

Inside of the *track* method get the coordinates of the mouse as follows:

```
b.x = mevt.getX();
b.y = mevt.getY();
```

and see what your program does. (Probably nothing - you still have to erase the old balloon, before you make the changes, paint the new balloon, and as a courtesy, set the view state for the view.) Now you should have fun.
